A. P. BLESING,
Minister of Agriculture.

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Congress.

The forty-fourth Congress of the Agricultural Bureau will be opened by His Excellency the Governor at 8 pm. on Monday, September 11th, in the Way Hall, Franklin Street, Adelaide. Addresses will be delivered the same evening by the Minister of Agriculture (Hon. A. P. Blesing, M.L.C.) and the Chairman of the Advisory Board of Agriculture (Mr. A. J. Cooke). Delegates and other members of Branches are requested to be in attendance at 7.45 p.m.

Sessions for Women's and Men's Branches will be held on Tuesday morning, afternoon, and night, Wednesday morning (Free Parliament), and Wednesday night.

Agricultural Bureau Conferences.

Branches of the Agricultural Bureau have been advised that District Conferences will be held as follows:—

Pinnaroo Line, at Parilla, Tuesday, September 26th (Secretary, Mr. J. W. D. Carman) (altered).

Murray Lands (East), at Taplan, Thursday, September 28th. (Secretary, Mr. P. R. Hodge, Nangari) (altered).

Eyre's Peninsula (Southern), at Cummins, Wednesday, October 4th. (Secretary, Mr. H. M. Roberts.)

Eyre's Peninsula (Central), at Minnipa, Friday, October 6th. (Secretary, Mr. D. V. Kitto.)

Each Conference will commence at 10.30 a.m.

Butterfat Output Competition.

The United Dairy Cattle Breeders' Association of South Australia some six years ago inaugurated a Butterfat Output Competition, which has been known ever since to members of the association as the Gold Medal Competition. It is open to all members who have at least six cows under official test, and the results based on the official figures are computed and supplied annually by the Department of Agriculture.

In the main, the rules have not varied a great deal over the period of years, although one alteration made in the year just closed seemed to increase the tensify for some entrants and to reduce it for others. The rule in question was the one affecting the personnel of the herd, and requiring that at least one cow in every six or part thereof should be 5 years old or over. Such a rule had the effect of giving to the herd with the specified number of mature cows a decided advantage over the one which possessed too few, and in certain instances of relatively small herds in which the quota of mature cows lacked considerably, these herds were not eligible to compete. This anomaly, however, was removed in time for the sixth year, and the rules for that year, which ended on June 30th last, were as follows:—

1. At least six cows per herd had to be entered for the competition.
2. In herds of more than six cows, owners were permitted to withhold from competition 25 per cent. of their number, but not more than 25 per cent.
3. Handicaps were:—

For cows under 2 years at calving, 80lbs. butterfat.

Two years, but under 3 years at calving, 60lbs. butterfat.

Three years, but under 4 years at calving, 40lbs. butterfat.

Four years, but under 5 years at calving, 20lbs. butterfat.

Five years and over, nil.

The final results have brought to the fore a new winner in the person of Mr. C. E. Vereco, of Mount Compass; his herd, a comparatively small one, established a new record output for this particular competition.

The winners to date have been:—

- 1927-28 Mr. C. J. Morris, Monteith, 556.58lbs. butterfat.
- 1928-29 Mr. J. A. J. Pfitzner, Hampden, 456.81lbs. butterfat.
- 1929-30 Mr. C. J. Morris, Monteith, 496.69lbs. butterfat.
- 1930-31 Mr. C. J. Morris, Monteith, 465.21lbs. butterfat.
- 1931-32 Mr. C. J. Morris, Monteith, 560.94lbs. butterfat.
- 1932-33 Mr. C. E. Vereco, Mount Compass, 563.47lbs. butterfat.

The Late Professor Lowrie.

The recent death of Professor William Lowrie recalls to the minds of all farmers the valuable work which the late Professor achieved for South Australia. He was known personally to many as an able man of great personality, and the younger generation of farmers learnt to recognise him as a leader in agriculture and one whose work exercised a powerful influence on the agricultural practices of this State. As a tribute to the Professor the following remarks were made by the Minister of Agriculture (Hon. A. P. Blesing, M.L.C.) at the opening of the Winter School for Farmers at Roseworthy Agricultural College early this month:—"It is appropriate on this occasion to draw attention to the recent demise of Professor William Lowrie, who occupied the position of Principal of the Roseworthy Agricultural College with conspicuous success from 1887 to 1901. Concerning his College work, it can be said that during the course of those 14 years he laid down well and truly the foundations upon which the College work has since developed, and that he was responsible for the training of many students who have since risen to distinction in various walks of life. But he did far more than this. In Lowrie's time there was no Department of Agriculture; in fact, at that time the Roseworthy Agricultural College, meagrely equipped as it was, may be said to have been the Department of Agriculture. Lowrie was both a man of conspicuous ability and a practically minded farmer; he paid close attention to farm operations on the College farm; he sought to account for the relatively low wheat yields that were prevalent at the time. Eventually he came to attribute them to two main factors more or less related to our climatic conditions, namely:—(1) Efficient bare fallow, and (2) the systematic use of water soluble phosphates. As soon as he had convinced himself of the soundness of his facts, he stressed their importance to South Australia from platforms in every section of our agricultural areas. His advocacy was so successful in the matter that our mean wheat yields which for the 30 years ending in 1906 were below 6bush. to the acre rose to 9½bush. in the next decade and to 12½bush. in the decade that followed.

It can be said, of course, that land was being fallowed in South Australia before Lowrie's time, and that response of the College land to superphosphate had already been noted by his immediate predecessor, Professor Custance, and this no doubt is true. But farmers of the present day whose personal experience does not extend to the eighties can have no idea of the difference between 'fallow' as Lowrie conceived it—and as we accept it to-day—and 'fallow' currently practised by farmers of the eighties. Lowrie was the first to show how 'bare fallow' should be prepared and handled in South Australia; and to-day Lowrie's bare fallowing is the sheet anchor of South Australian farming. Further, more than any other man, Lowrie, by the effectiveness of his advocacy, was responsible for the rapid adoption of drills and superphosphate in South Australia. His name and fame should be an inspiration to all young South Australian farmers."

Worms in Horses.

At the recent Conference of Upper Northern Branches of the Agricultural Bureau a delegate from Morehard asked: "What is the cause and treatment of large white worms, very prevalent in young horses this year? Mr. R. H. F. Macindoe, B.V.Sc.,

M.B.C.V.S., to whom the question was submitted, says:—"Infestation of horses is the result of their swallowing the eggs of the worms contained in food or water. The eggs develop under favorable conditions of warmth and moisture such as would be supplied in moist earth at a temperature of 98deg. Fahr. They retain their fertility in unfavorable surroundings for a long time and develop under favorable conditions. The young worm in the egg can live in dry horse manure for six months. *Treatment for Horses with Large White Worms.*—Withhold all bulky food for 24 to 48 hours, but bran mash with a little crushed grain can be given. Then administer as a drench:—Raw linseed oil, 1½ pints; oil or turpentine, 4 to 6 table-spoonfuls. Shake thoroughly before administration. Withhold all food for two hours after drenching and then give a small feed, gradually increasing the amount until the animal's normal ration has been reached. Tartar emetic in one dram doses repeated at the end of 12 hours and given with a little linseed meal in a small bran mash, followed in 24 hours by an oil drench, is also effective, but do not give the oil drench if diarrhoea is present. *Preventive Measures.*—All worms expelled should be burnt. All drinking water should be protected from contamination with manure and as free from surface drainage as possible."

Oranges Setting Fruit out of Season.

Replying to a question, submitted by the Upper Northern Conference as to the cause of orange trees setting fruit out of season? Mr. G. Quinn (Chief Horticultural Instructor) says:—"Whilst the normal flowering period of the orange tree is in spring when the first burst of new growth occurs, it will, if stimulated to make further bursts of new growth, produce flowers and set scattered fruits at any time during the summer season. This characteristic may be explained by pointing out that orange trees do not develop flower buds on the previous summer's growth before the trees go to rest—as is seen in the case with the deciduous fruit trees such as apple, pear, peach, apricot, cherry, plum, &c., but the flowers are formed on the ends of new shoots and set into fruits without any delay or resting period.

The usual cause for a succession of fruits forming on the orange trees is that after the growth, which begun in the spring, has matured, the ground may become somewhat dried out and the roots cease growing. A soaking rain or an irrigation applied at this stage causes a renewal growth of young shoots which often blossom and set some fruits. In our dry summer climate such intermittent supplies of moisture may cause several bursts of new growths and flowers, and result in a tree carrying several lots of fruits, all of varying sizes and ripenesses. The best way to avoid these recurring settings of fruit is to maintain enough moisture in the soil until after midsummer to prevent these fits and starts of new growths. It is wiser to test the moisture in the soil about the trees by boring or digging a hole here and there, than to be guided by the curling of the leaves of the orange tree which is usually a sign that its roots are suffering from lack of soil moisture."

AGRICULTURAL INQUIRIES.

[Replies supplied by Mr. W. J. SPAFFORD, Deputy Director of Agriculture.]

Weevil in Wheat.

Woolville Agricultural Bureau—"Will dry pickle kill wheat weevils?"

Reply.—It is a matter of common experience that where seed wheat is pickled with copper sulphate powder, and the work is done in a barn, the building is rid of weevils.

The fine powder settling on walls and beams kills the insects and prevents re-infection from outside sources. The department has no knowledge of experiments carried out to show how little copper carbonate would be effective in killing weevil in grain, but in any case this method of eradicating the insects could only be practised with wheat that is to be used for seed, because copper carbonate in quantity is poison. Wheat that is to be used for feeding to animals can be kept free from weevils if stored in an airtight receptacle.

Ploughing in Stubble.

Palabie Agricultural Bureau—"Would ploughing in of 3bush. stubble be detrimental to fallow?"

Reply.—If the low yield of 3bush. per acre was due to the crop having been affected by "take-all," the ploughing in of the stubble would be harmful. In this case the land should have been cultivated instead of ploughed so as to leave the straw and other organic matter on the surface. On the other hand, if the low yield was due to lack of rain or poverty of the soil the ploughing in of the small amount of straw would not do much harm.

Working Red Land.

Palabie Agricultural Bureau—"The best method of working land, red sandy loam, ploughed August, 1932, worked back to depth of 2½ in. July, 1933, to be drilled in about May, 1934."

Reply.—If sheep are available they should have access to the fallow often enough to keep down all growth, then it will only be necessary to work the land when a crust has formed after fairly heavy rain. When the land is free from weeds a spring-tine cultivator with alternate tines removed will break the crust without smoothing the surface of the sandy soil to too great an extent, but if weeds are present the rigid-tine cultivator is the only implement to do the job properly without unduly encouraging drift. Under no circumstances whatever should the depth of cultivation given to this land exceed the 2½ in. of the working back.

Establishment of Artichokes.

Replying to an inquiry from Gulnare, Mr. Spafford states that there are two totally different plants known as artichoke which are used as vegetables. The globe artichoke is a thistle, the portion eaten by human beings being the base of the flower heads, whilst the other, generally known as the Jerusalem artichoke, produces tubers which are cooked like potatoes. The roadside weed known as wild artichoke is a thistle, very similar in appearance to the globe artichoke, but is very spiny, and except for the spines is a livestock foodstuff of fair feeding value. Stock do quite well on the wild artichoke if converted into ensilage, and readily eat the plants if they be cut and allowed to wilt before being placed before the animals. There is a form of the wild artichoke which is free from spines and is readily eaten by farm livestock.

Boiled versus Crushed Grain for Stock.

Weavers Agricultural Bureau—"Is it advisable to boil grain for stock, or is crushing best?"

Reply.—It is generally recognised that hardly any of the ordinary livestock foodstuffs are improved by boiling and that, with the exception of potatoes, it is not an economic practice. Best results are secured from grains by grinding to a fine meal; soaking gives slightly better results than feeding whole, dry grain. Cooking lowers digestibility, although it sometimes improves palatability. If grains are to be soaked, only sufficient water to be absorbed by the grain should be added, and there should never be a surplus of water. Soaked grain should be fed when fresh and not allowed to become sour.

Growing of a Wheat Crop on Irrigated Land.

Pompoota asks for information regarding the growing of a crop of wheat on irrigated land.

Reply.—It would be easy enough to grow a crop of wheat for hay with irrigation on swamp land, but it is doubtful whether one could be certain of a crop of grain. When growing wheat under such conditions there is very grave risk of red rust destroying the crop for all purposes, and if an attempt is made to grow a crop for grain it may have to be cut for hay at short notice. Without being at all confident that the crop will be successful, the following is suggested:—

Best Variety to Sow.—Of the prominent wheats of the State there are only two that are very rust-resistant—Ford and Sword. Although rust-resistant under ordinary field conditions, it could not be expected that they would retain this resistance on swamp land, but they should be better than other kinds; 60lbs. seed per acre should be ample. Although rank growth could be obtained without manure, the addition of 60lbs. to 90lbs. superphosphate per acre should be beneficial. If the crop does mature grain, it is certain to be so rank that it is very doubtful if a stripper could possibly handle it. A reaper-thresher would harvest the crop, otherwise it would be necessary to cut with binder and then thresh it in some way. For almost all conditions the best depth to sow seed wheat is about 1in. If planted by the middle of July and the crop matures normally, it should be ripe towards the end of December. If the land is at all damp at seeding time there will be no need to irrigate to promote germination, but if the land is dry it should be irrigated, and as soon as dry enough to take the team, it should be cultivated and sown. Where the watertable is so close to the surface, as it is in many parts of Pompoota, the greatest difficulty is likely to be keeping down excessively rank growth and to reduce moisture from around the plants, and it is doubtful if any irrigations will be required.

TOP BRAND FERTILIZERS.

15/- per ton REBATE.

Purchasers of **TOP BRAND FERTILIZERS** are advised that 15/- per ton is being paid by the Federal Government on all Fertilizers used in the production of Primary Produce, other than Wheat, during the period, 1st December, 1932, to 30th November, 1933.

The Adelaide Chemical & Fertilizer Co. Ltd.

Royal Chambers, Currie Street, Adelaide.

Eradication of Soursobs.

Bowmans asks for information concerning the control of soursobs.

Reply.—The only successful method I have seen of controlling soursobs, which appear in quantity on cultivated stubble land, is to cut them off with a rigid-tined cultivator every time they appear, and delay seeding as long as possible and seed land with an early variety of wheat, such as Gluyas or Waratah. If they persist well into the winter, it may be necessary to keep at them until after the safe-seeding period for wheat has passed, then either Prior (2-rowed) or Roseworthy Oregon (6-rowed) barley could be sown. Barley tends to choke out soursobs much more effectively than any other of the cereals.

Soursobs, no matter how thick, do not interfere with the job of ploughing to any great extent, and as it is well to expose as many of the bulbs as possible the original stirring of the fallow should be given with a mouldboard plough. Very little can be done towards eradicating the weed during the spring and summer, unless pigs or turkeys are to be run on the land to help control the pest, when the more frequent the workings given the more bulbs will be exposed for the animals and birds to eat. As soon as the autumn rains arrive, a growth of soursobs appears, and to thin out the weeds it is necessary to cultivate every time the soil shows green. Seeding should be delayed and very early varieties of wheat used. The rigid-tined cultivator fitted with wide shares is the best implement to use to deal with soursobs.

Soursobs sometimes injuriously affect sheep when fed almost exclusively upon them for long periods of time, but provided the sheep are not hungry when first put on a luxuriant growth of soursobs little harm is usually experienced.

Soursobs are a nasty weed to have on a wheat-growing farm, and where present, farmers are almost compelled to delay seeding to enable them to frequently cut off the growth, and then to sow very early varieties of wheat.

VETERINARY INQUIRIES.

[Replies Supplied by Veterinary Officers of the Stock and Brands Department.]

Upper North Conference: "Has the Department any knowledge of a disease in the Flinders Range known as coast disease on Eyre's Peninsula?"

Reply.—The term "coast disease" has been applied in a wide sense by stockowners on Eyre's Peninsula, Kangaroo Island, and other coastal areas of the State to a variety of diseases seen principally in sheep, the symptoms of which are weakness and debility which may be accompanied by diarrhoea, in some cases associated with some inco-ordination of movement, and in other cases fragility of bones. These symptoms, however, may be brought about by a variety of causes, such as (1) internal parasites, (2) a mineral deficiency in the diet, (3) the ingestion of certain plants (which causes interference with nerve function), and on Eyre's Peninsula and Kangaroo Island there is a disease also included under the general term "coast disease," in which the sheep appear weak, possess no energy, and lose condition rapidly, but if transferred from the limestone country (where disease is always noticed to occur) on to ironstone country, recovery takes place. This means that the term "coast disease" as used by stockowners on Eyre's Peninsula and in other parts of the State does not define one specific disease, but is applied to at least four diseases which in many respects have some similarity in symptoms, e.g., weakness and debility. The Stock and Brands Department has no knowledge of a disease in the Flinders Range which resembles the diseases found on Eyre's Peninsula, but in heavy rainfall areas it is probable that internal parasites may be causing mortality and economic losses.

Upper North Conference: "How may corns be diagnosed on horses and what is the treatment?"

Reply.—The term "corn" is applied to a bruising of the sensitive sole situated between the bars and the hoof wall, which is always due to pressure brought about by the heel of the shoe pressing down on this part of the sole. The injury may

Always say LAUREL not just kerosene

These Laurel cans in three sizes (quart, half-gallon, and 4 gallon) are wonderfully handy. Get one. You will be delighted with it and with Laurel too.

VACUUM OIL COMPANY PTY. LTD.

cause a rupture of minute blood vessels in the sensitive sole and the blood escaping stains the fibres of the horny (insensitive) sole. If the injury to the part is severe or long continued and no attention is given to it, suppuration may supervene and then a festering corn is established. *Diagnosis*—The presence of corns will cause “nodding lameness,” but as other injuries below the region of the knee cause a similar symptom, it is always necessary to examine the foot of the affected leg to establish the diagnosis. *Treatment*—Remove the shoe or shoes, cut out the tissue lying between the bar and the wall, and apply a poultice. If pus (matter) is present, sufficient tissue should be removed to effect proper drainage (otherwise the pus will work upward and break out on top of the heels). The wound should then be syringed out or soaked in solution of lysol and water (2 tablespoonfuls of lysol to 1 pint of warm water) and then for three or four days placed in a bran poultice, removing and treating daily as outlined above. When lameness has disappeared, have the animal shod with shoes which do not apply weight on sole between bars and hoof wall. This can be done by either (1) a three-quarter shoe, which is a shoe without a heel, or (2) “seating” the shoe so that the weight is carried on the junction of the wall and sole only.

Upper North Conference: “Is it advisable to bandage the legs of a foal that has been born with weak joints and what class of a bandage would be suitable?”

Reply—It is difficult to reply to this question, as the treatment to be given depends largely on the symptoms exhibited. Often in blood stock foals which knuckle over badly are born, and in such cases the legs should be placed in splints which can be made from hoop iron encased in cotton wool, carried from below the knee down to the hoof, under it, and up to back of the knee and kept in place by bandages, but considerable ingenuity is required in fixing and keeping the splints in position.

Eastern Eyre’s Peninsula Conference: “What is the best remedy for a horse with worms, and to build up constitution?”

Reply—The treatment usually advised for parasitic infestation of the horse (farin type) is as follows:—(1) Starve the horse for 24 hours (no feed or water to be allowed). (2) At the end of that time give the following drench:—Raw linseed oil, 1½ pints; oil of turpentine, 2ozs. (3) Subsequently feed on good quality chaff, bran, and oats. Feed regularly. The feeding is very important. (4) Further, give 1 tablespoonful of Fowler’s solution of arsenic in a small damped feed night and morning for 14 days. Buy Fowler’s solution of arsenic in 1lb. bottles.

RED SCALE.

The Chief Horticultural Instructor (Mr. G. Quinn) has identified an insect sent to the Department of Agriculture by the Longwood Branch of the Agricultural Bureau as red or orange scale (*Aspidiotus aurantii*), and discussing methods for its control says the best remedy is to enclose the tree in a gas-tight fumigating sheet and fumigate it with hydrocyanic acid gas—prussic acid fumes—for 45 minutes. As this is a procedure fraught with some danger, it should only be done by experienced operators. The equipment also, as a rule, is only possessed by regular orchard fumigating contractors or association.

The next best remedy is to spray the affected trees with an oil emulsion, such as kerosene emulsion in soap, or one of the white summer spraying oils, or with resin wash. This work is best done during the summer months when the young scales are crawling about the trees, but in no case should a tree be sprayed unless there is abundance of moisture in the ground at the time, either from a recent rain or an irrigation.

If the trees are very dense, they should be first thinned out to permit the spray being applied to every part of the twigs and foliage. Two or more thorough sprayings are required each season to keep the scale thoroughly under control.

ANIMAL BREEDING PAST AND PRESENT, WITH SPECIAL REFERENCE TO THE WORK OF ROBERT BAKEWELL.

*[Address by Dr. A. R. Callaghan (Principal of Roseworthy Agricultural College)
to the Annual Meeting of the S.A. Branch of the Australian Society of
Breeders of British Sheep.]*

Those of you who are familiar with the history of animal breeding, and the enormous theoretical developments in the subject within the present century, will feel truly sympathetic towards me, especially when you realise that I have to cover the story in the very short time allowance of about half an hour. Without wasting time, therefore, I wish to state at the outset that my main endeavor this evening will be to put your minds at ease on the subject of animal breeding as an applied science, for although by training I feel that I am more or less wedded to genetics, which is symbolised by Mendelism, I cannot see how I can help you as practical animal breeders beyond confirming your suspicions that certain old beliefs are false. If I had an hour and a half at my disposal I could guarantee to confuse you to such an extent that you would never open another text-book on the scientific principles of breeding for the rest of your lives. In fact there is no subject which lends itself so well to baffling one's listeners with science than that which has developed to explain the intricacies of heredity. Recently I received an inquiry from a sheep farmer interested in this subject; his letter indicated intense interest, combined however with a certain amount of hopelessness because he was unable to get anyone competent to give him a simple explanation of genetics. He pleaded and asked if I would put him on to the simplest and the best article on the subject. I referred him to the simplest and most up-to-date work I knew, stating in parenthesis that it was a book of approximately 500 pages.

I can divide my talk this evening into two main categories—the first deals with our knowledge of breeding before the opening of the present century, and includes the old theories, and the second deals with the development since 1900, and includes our modern conception of heredity.

The old theories can be traced back to thousands of years B.C., in fact they have their foundations in the first domestication of animals by man, which is well beyond the realms of ancient history. Skipping the dim ages I propose to commence our review with the days when Adam was a mere boy. Some of you will recall that Adam and Eve had two sons—one Cain, the other, Abel—and in the fourth Chapter of Genesis we read, "And in the process of time it came to pass that Cain brought of the fruit of the ground an offering unto the Lord, and Abel, he also brought of the firstlings of his flock and of the fat thereof. And the Lord had respect unto Abel and his offering, but to Cain and his offering he had not respect." My contention is, gentlemen, that Abel knew more about his job of animal breeding than Cain did about his job of agriculture.

This superiority of animal breeders over the agriculturists in the practice of their art continued through thousands of years, and I doubt very much whether the agriculturist has caught up even yet.

There is no doubt whatever that the knowledge of animal breeding is one of the greatest, if not the greatest, traditions of mankind; it has developed in snow-ball fashion through the ages, accumulating from one generation to another. It has developed because of man's close association with animals; this association probably began by sheer companionship, for we are told that the dog was one of the first to be domesticated. Soon man, the true egotist, conceived the idea of keeping animals for his use, and from that stage on there has been a steady increase

in the value and usefulness of the animals he domesticated, so much so that the original wild types are unknown to us in the majority of cases, and we are left to theorise on the probable type and conformation of their wild ancestors.

All this time a great art was developing, and we of the present day are practising that art as it has been handed down to us. Mistake me not, gentlemen, for I mean art, and not science, for I am certain that we in this generation will never be privileged to indulge in any exact science of animal breeding as applied to the major groups of our domestic animals, for our present artistry is greater than our present science as far as this aspect of breeding is concerned.

Naturally man put his reasoning powers into operation in connection with the breeding of his animals, and he began to theorise, and until comparatively recent years this is where he failed. He was following certain methods because he or his predecessors had had success with them, but the details of heredity baffled him.

The first great advances were when he first controlled parentage, and this goes back at least 2,000 years B.C. We know that Sheik Salaman of the Arabians owned five famous mares about 1635 B.C., from which the best Arabian horses have been descended. In passing it is of interest to note that it is known that the Arabs, even in these early days, practised artificial insemination. From these early periods the great theory, "like begets like" was handed down, and was the rule of thumb of all breeders. Practically no new developments ensued until Robert Bakewell, of Dishley Hall, walked on to the stage in 1760 to play his part, and all authorities agree that the development of modern breeding dates from 1760 when Robert Bakewell began his wonderful work, for it was he who actually laid the foundation upon which most of our modern breeds of livestock have been developed.

This leads me to one of the main objects of my talk to you this evening, that is to pay homage to Robert Bakewell, a distant relative of Messrs. H. K. and R. D. Bakewell, of the Yalkuri Pastoral Company, who are members of our S.A. Branch

Auction Sale of Subsidized Bulls.

THE ANNUAL SALE

of Pure-bred Bulls eligible for Government Subsidy will, as usual,
be held on the

Royal Show Grounds, Wayville West

ON THE

THURSDAY MORNING of SHOW WEEK.

It is anticipated that about 50 Bulls will be offered, comprising Ayrshires, Friesians, Shorthorns, and Jerseys, from the best herds in the State.

On each of these Bulls Government offers as a subsidy to the buyer, a sum equal to 50 per cent. of the purchase price, the maximum subsidy per bull being £25.

For further particulars enquire at the Department of Agriculture, Adelaide; or at the office of the Auctioneers, COLES BROS, Ltd., 70 Currie Street.

Authorized by the Advisory Committee for Improvement of Dairying.

of this society and are present with us this evening. Surely it is rather unique that this our S.A. Branch should have an almost direct connection such as this with the founder of modern breeding. I say almost direct connection for the simple and trustworthy reason that the famous Robert Bakewell was a bachelor.

I could well spend the rest of my allotted time this evening in discussing the character and ability of Robert Bakewell. I could tell you how he proceeded on his farm, introduced rare and original methods of agriculture, how he irrigated his pastures, and utilised the resources at his disposal to their fullest and best advantage, and to what lengths and pains he went to breed and nurture the best sheep, the best cattle, the best horses, and the best swine he could from the foundational material available to him. Interesting as all this might be it would not serve my purpose of portraying Bakewell as a master of the art of breeding, and placing his work before you in its maturest and truest perspective.

All the biographers of Bakewell give him an exemplary character; in fact only the one blemish to his character is recorded, a most excusable one at such a meeting as this, for he was accused of possessing a certain degree of acquired cunning which the biographer excuses on the basis that "it is the recognised vice of his profession." Like the breeders of to-day he had a store of anecdotes and stories, but differed from many in that his conversation was never disgraced with expletives. Further we learn that he was a man of unimpeachable morals, and a person of strong natural sagacity. My general impression of this man from what I have read is that he was a born experimentalist, attended to all his work with infinite pains and the greatest of detail, was willing to impart all he could to those in sympathy with him, yet had insufficient education to hand down his methods, ideas, and reasonings to posterity, by means of his own pen. I feel certain that had Robert Bakewell been a fully educated man, the world would have been the richer, for it would not have been left to others to record the story of his magnificent achievements.

Bakewell's most distinguished success was unquestionably the formation of the Dishley or New Leicester sheep, a work which will remain a classic in the annals of livestock breeding. This work with the Leicester, or English Leicester, as we know it in Australia, was a pioneering work of the greatest importance, and his efforts and extraordinary success paved the way to the improvement of all our breeds of sheep, and in fact all our breeds of livestock. Bakewell realised and convincingly demonstrated in this work that animals have the power of transmitting their good qualities to their progeny, and that if proper care and attention be paid to mating and selection the desired type can be obtained.

His initial step was to choose carefully and critically the animals for his foundation, those which satisfied him most from the point of view of the design and proportions which were in his own head. Having selected and purchased the best of all that could be found of the county sheep he then set about propagating his own without seeking further blood from outside, for trusting in his early judgment which guided his initial selections, he felt that there was no stock good enough to mate with his own again. As one author puts it, "There may have been an odd sire in some odd place as good, but Bakewell could not be running constantly to Westmorland for a bull, Lincoln for a ram, or Holland for a stallion. He therefore began to put his own stock to his own, and continued to do so until the end of his career." Such a practice of breeding within his own flock was greatly at variance with the belief of the times, in fact it shocked the populace to learn that he was even practising the closest of in-breeding with some of his sheep, mating sire and daughter, dam and son, brother and sister, and so on. It shocked their morals chiefly, and those writers of the time who attempted to describe his system had eventually to adopt defensive tactics. To my mind the method of close breeding which he adopted was the greatest single contribution Bakewell made to animal breeding.

Apart altogether from this, however, he paid particularly close attention to symmetry and utility of form, smallness of bone, early maturity, and good fattening qualities. These aspects of his ideal sheep he made his objective, and his greatness lies in the fact that he obtained his objective to his complete satisfaction. The Leicesters which he bred, although slightly smaller in frame than the original foundational sheep, were greatly improved in compactness and symmetry of form, were thicker and deeper, and possessed of great fattening qualities, as well as early maturity.

Summarising the outstanding features of Bakewell's work in this connection it can be said that he had an innate judgment of form and external appearance which enabled him to discern the qualities he desired in the material available for selection. He was able to discriminate between size and quality of carcass, and he perceived a relationship or correlation between outward form and the aptitude to fatten and develop quickly. In other words he defined type as we know it to-day, and realised the true basis of utility of form.

Unwittingly Bakewell followed the underlying biological principles which control all breeding, and if our present knowledge of heredity had been available at the time, no sounder principles could have been adopted for the establishment of a definite type of new breed.

Leaving Bakewell I desire to relate very briefly how our knowledge has developed since his time. Needless to say, Bakewell's methods gradually became known and adopted, and the names of many accomplished breeders since his time might be mentioned, but actually they were interpreters of the system laid down by him. Of these I might mention Culley Brothers, as founders of the Border Leicester, and Thomas Ellman, who laid the basis for the modern excellence of the Southdown, as perhaps the outstanding men. The art continued to develop, and its refinements became more and more generally adopted, and outstanding progress was made. Along with this progress, however, there evolved a keen sense of inquiry and desire to know just how the mechanism of heredity worked.

About 1800 Lamarck made the inheritance of acquired characters the basis of a theory of evolution. Briefly his theory was that a new environment created new desires, created more activity on the part of some organs than others, and generally gave stimulus to new characters to fit the new environment, until gradually, after a number of generations, certain characters changed form and were eventually inherited. Darwin supported this hypothesis, and attempted an explanation on the basis that the cells of the body influenced in some way the reproductive cells, so that body changes would be inherited in the progeny. He had no proof nor could he show how such could take place.

35, CURRIE STREET ————— ADELAIDE.

Other men brought several theories to bear on the subject which played a big part in our present conception, but the most highly developed and convincing of all theories was that postulated by Weismann in 1892, and which is now known as the theory of the continuity of the germ plasm. He did not believe in the inheritance of acquired characters, and maintained that the germ plasm which gives rise to the sperms and egg cells of living organisms remains unchanged and is handed down by the body unchanged and intact to the germ cells. He attacked the theory of Lamarck and Darwin, and pointed out that the evidence they gave was inconclusive. You and I know, gentlemen, that certain body modifications acquired during life are most certainly not inherited, and, to put it bluntly, I usually point out that wooden legs are not inherited, but wooden heads are.

Weismann searched for a proof, but it was left to subsequent investigators to prove that he was correct and that a mechanism did exist whereby the germ plasm maintained its complete identity.

The next great advance was made by Hugo de Vries when he advanced his "Mutation theory." De Vries became so convinced of the general occurrence and significance of suddenly appearing heritable variations that he proposed a theory of evolution by mutation in which he applied Darwin's great principle of natural selection. Without some change in the germ plasm it was difficult to explain how new characters suddenly appeared, but de Vries theory now universally displaced the old theory of the inheritance of acquired characters.

The discovery of Mendel's laws, which were first interpreted and made known to the world in 1900, although Mendel's original paper was published in 1865, revolutionised all ideas which were current at the time on inheritance, and for the first time a clear and lucid picture of the inheritance of certain characters was given. Weismann's theory of the continuity of the germ plasm stood the test better than any other theory, and with slight modifications the inheritance of characters on the basis of the continuity of germ plasm is well established.

The discovery of chromosomes made possible by the development of the microscope actually proved that a mechanism for inheritance along the lines interpreted by Mendel did exist.

From Mendel's work an enormous and all absorbing science has developed, and its application to all known organisms, plants and animals, high and low, and even to man, has been definitely proved. We now realise that we depend upon our parents for our hereditary constitution just as much as the sheep that are bred by you depend upon their parents for their hereditary constitution.

And so during the last 30 years the new science of genetics has developed, phenomenal advances have been made in our knowledge of heredity and its physical mechanism, but as far as animal breeding is concerned genetics has so far only elucidated the "whys and wherefores" of animal breeding, it has not contributed greatly to the "how" of animal breeding, that is still the gift of the breeder. From our knowledge of genetics, however, we receive confidence, for the light that has come through our new knowledge has merely confirmed the best methods of the past and disproved the worst, and it bears witness to the soundness and genius of the most noted of our earlier animal breeders, amongst whom Robert Bakewell ranks supreme as the first great pioneer of the modern art.

Out of the successes and failures of the past the wonderful art that is known and practised by breeders of livestock has been fashioned. Even the most ardent geneticist must admit that animal breeding is more of an art or a craft than an applied science. The time will come, there is little doubt, when science will be applied to animal breeding with full and lasting consequences, but underlying every success will be the artfulness or the craftsmanship of the traditional animal breeder.

THE PRODUCTION OF FAT LAMBS FOR LOCAL AND EXPORT TRADE.

[Prepared for the South Australian Branch of the Australian Society of Breeders of British Sheep by Dr. A. R. Callaghan, Principal of Roseworthy Agricultural College, assisted by Mr. S. Whicker, Livestock Assistant, Roseworthy Agricultural College.]

For the man about to interest himself in the production of fat lambs there are two main considerations with which he is confronted at the outset; the first is the class of country at his disposal and the second is the class of sheep he should use.

The first of these leaves very little to choice as the country is usually a fixed factor as far as the producer is concerned and he is anxious to know how to proceed on the country already in his possession. Provided the holding is reasonably convenient to market, or facilities of transport to market are accessible, and

Fig. 1.—Border Leicester.

there is an assurance of winter feed, he can proceed with confidence. The very nature of our climate fits in with the idea of fat lamb production, for a period of feed shortage is followed by a period of excessive feed. The breeding of lambs to eat and fatten during the winter months when pasture is plentiful and selling them off the place again before the grass becomes scarce or dry and seedy, actually enables the grower to balance his carrying capacity, or utilise it to the fullest extent without having to run the risk of overstocking, or pursue an unsound policy of understocking. Under the environmental conditions prevailing in our main agricultural areas, therefore, fat lamb production has not only a definite place in our agriculture, but also a definite appeal to pastoralist and farmer alike.

CHOICE OF BREEDS.

The class of sheep at the disposal of the fat lamb producer is by no means limited in kind, but there are only three classes of sheep at his disposal.

Firstly, there is the Merino, renowned for its wool and kept principally for this reason. Secondly, there is the longwool class of British breeds, all of which may be described as dual purpose types, that is, they have valuable characters of carcase for mutton purposes as well as valuable wool. Thirdly, there are the shortwoolled, purely mutton breeds of British sheep.

For the successful pursuance of first class fat lamb production all three classes are utilised, but they are not essential, as will be shown later.

The longwool class when used is mated to Merino ewes primarily for the production of half-bred ewes, and the wether progeny can best be disposed of as fat lambs. In this mating there is an idea of *permanency*, for the half-bred

Fig. 2.—Romney Marsh.

ewes thus bred become valuable sheep from the point of view of their fleeces as well as for breeding of lambs.

The shortwoolled British breeds are purely mutton sheep, and when mated as sires to either Merino or half-bred ewes the sole object of the breeding is production of lambs for slaughter, the crossbreeding in this case is definitely of a *temporary* nature.

The choice of a foundation flock at the outset is therefore confined to Merino ewes, but where possible the breeding of a half-bred flock by mating at least some of the Merino ewes to rams of one of the longwool breeds is very desirable. The longwool British breeds at the growers' disposal are Border Leicester, Romney Marsh, English Leicester, and Lincoln (see Figs. 1 to 4), any one of which will cross very satisfactorily with the Merino and give a large framed, good breeding type carrying a profitable fleece (see Fig. 5). For the purpose the grower might find it more profitable to purchase the half-bred longwool Merino ewes rather than breed them himself, but much would depend upon local and personal circumstances. Any one particular breed cannot be advocated here,

even if it were desired, but the climatic conditions greatly influence choice, and it would be quite erroneous to be emphatic on the merits of one breed over all others. One type of half-bred will flourish under one environment, whereas better results with another will be obtained invariably in a different district, so that in point of fact it is impossible to stipulate which is the best half-bred to run unless the specific conditions are known.

It is generally recognised that, in the more favorable agricultural areas where fairly cold conditions prevail during the winter months, the half-bred longwool Merino ewe is an ideal type for fat lamb production, especially when mated with shortwool rams. There are many reasons for this, and briefly they may be summarised as follows:—

- (a) They are prolific, and capable of rearing twin lambs when twin lambs are born to them.
- (b) They are excellent mothers, foster their lambs well, and provide them with a plentiful supply of milk; this latter feature is important.

Fig. 3.—English Leicester.

- (c) They produce lambs of excellent conformation and capable of early maturity.
- (d) They carry fleeces of good weight and quality, and as they are a permanent feature of the work, this is a very important asset, which must be kept well in mind.
- (e) They can be mated to the rams as two-tooth, and with any of the short wool mutton breeds they nick well without any parturition complications.
- (f) They are ideal for more closely settled regions, being thrifty and good doers in small areas, not requiring the large, open runs that the Merino thrives best in, and, further, they have a natural aptitude to fatten even as broken-mouthed sheep, and, consequently, can be disposed of very profitably as mutton after their main period of breeding usefulness has finished.

Such a line of half-bred ewes is, however, not easily procured, but a flock can be easily bred up without seriously interfering with the immediate object of fat lamb production.

In the hotter and drier districts, where the sheep runs are larger, it is doubtful whether any breed is more suitable than the Merino as the basal flock. Provided the Merino is of the large-framed, plain-bodied, true South Australian type, excellent results can be obtained when these are mated to certain of the short woolled British breeds.

Where Corriedales are available they make an excellent foundation flock, giving excellent wool returns and fulfilling most of the desirable qualities of the half-bred longwool-Merino. When mated to the shortwool rams they produce splendid lambs.

The sires for fat lamb production for the best results must be drawn from the shortwoolled British breeds, and the following are available from which the grower must make his choice:- Southdown, Dorset Horn, Suffolk, Shropshire, Ryeland, and Hampshire (see Figs. 6-11). Undoubtedly certain breeds will give better results for export than others, and similarly other breeds will give better or at least as satisfactory results for the local market. It is possible here to be

Fig. 4.—Lincoln.

more definite in making general recommendations, but it is more expedient to leave the choice of the sire to the particular fancy of the breeder and suitability to the district concerned. Much will depend upon whether Merinos are being used as dams, or what type of longwool-half-bred Merino is being used. Suffice it is to say that compactness and shapeliness of carcass is the objective, and provided any particular breed gives a satisfactory lambing percentage, is sufficiently prepotent to give shapeliness, and compactness to his progeny, as well as early maturity, excellent results will follow.

The shortwoolled breeds mentioned, generally speaking, fulfil these requirements. Obviously, the choice of the ram within the breed is very important, and due attention should be paid to shortness of leg, well filled breech, and low set carcass generally, with good heart and lung room.

Whatever the choice, it is preferable to use one breed of ram in the flock, as uniformity of type is one of the main features of successful marketing. (See Fig. 12).

MANAGEMENT.

Having decided the line of breeding to be followed is but the first step in successful lamb raising, and whatever the breeds intended to be mated proper and careful management is the keynote of success. It is this aspect of the industry that is apparently most neglected. Many growers go to no end of trouble to ascertain the right breeds to use, and having made the choice imagine that their chief work is done. Nothing could be further from the truth, as good lambs can only be produced with consistent results by paying great attention to all details of the management of the breeding flock and the ewes and lambs after parturition.

The following aspects of management which directly concern the fat lamb raiser must be given very careful consideration:—(a) Mating; (b) lambing; (c) lamb marking; (d) feeding; and (e) marketing.

Fig. 5.—A Long-wool Merino half-bred ewe.

(a) *Mating.*

The actual time of mating will depend upon anticipated feed supplies five months in advance; in other words, mating must be so arranged to ensure lambing when green feed is available in regular and increasing quantities. Generally speaking, green feed is available in our agricultural areas in May and even earlier, especially where stubble feed is available. On the assumption that fresh feed is usual about April 30th, then the ewes should be mated about November 30th, thus allowing for the five months' gestation period. Before this date it will be found difficult to mate longwool-Merino half-bred ewes, as they will not take the ram readily. This appears as a peculiarity of some breeds. Where early mating is required and considered reliable, the use of the Dorset Horn-Merino

half-bred will satisfy the requirements, as they mate readily at any time. The Dorset Horn is a breed more or less intermediate between the true shortwool British breeds and the longwool breeds, and when mated to the Merino they produce large-framed breeding ewes. As permanent flock 'sheep the half-bred Dorset Horn-Merinos yield a lower fleece return than the longwool-Merino half-breeds, but they are quite equal to them as mothers and for producing early-maturing lambs.

The rams of British breeds require to be young if satisfactory service is to be given, and they should be two, four, or six-tooth, but no older, for it can be taken as a general rule that British breed rams over three years of age are unreliable lamb getters. The rams should on no account be overfat, for in such condition they are lazy and prefer to sleep in spare moments when their activities are most required. They should, therefore, be in good, vigorous condition, and

Fig. 6.—Southdown.

to encourage this it is a good practice to allow them $\frac{1}{2}$ lb. of oats per head per day for about a week or 10 days before mating.

The ewes should also be in active condition, preferably in forward-store condition, gaining weight, but not fat; overfatness in the ewes makes conception difficult, chiefly because the organs become rather congested with excess fat. The best results follow what is known as "flushing" the ewes just prior to and during mating; this requires that they be run during this period on the freshest and most nourishing feed available. Green pickings, which are normally prevalent on fallows at this time, serve the purpose of flushing well, as the fallow grazing assures a certain amount of exercise as well as providing the necessary fresh feed.

In joining the rams it is preferable to yard the ewes; in this way the rams and ewes become acquainted more readily than if the initial meeting is in an open paddock. Any benefits which may accrue from "love at first sight" are taken the fullest advantage of by this method. About once a week during the mating period the ewes should be yarded into a convenient yard or small enclosure and the rams removed and given a feed of $\frac{1}{2}$ lb. oats. Re-introduce the rams

after their feed before nightfall and allow the flock to remain in overnight. This night yarding certainly speeds up the work of the rams and encourages a far more even lambing. After mating has proceeded for a fortnight or three weeks, provided facilities are available, it is a good policy to introduce a reserve ram to the flock while one of the others is removed and spelled for a time, or better, use half the number of rams one week and replace them the next week with the other half. The rams being spelled should be fed well in the meantime. Often the ewes that do not take particularly to the rams already in the flock will take kindly to a fresh ram, and *vice versa*, a fresh ram will pay greater attention to ewes that have not received such intimate attention from the other rams.

The mating period should continue for seven to nine weeks, when all the rams should be removed.

Fig. 7.—Dorset Horn

(b) *Lambing.*

About six weeks before the ewes are due to lamb they should be crutched. The crutching should extend from well above the tail down to the point of the hocks, as illustrated in Fig. 13; and in doing so the ewes should be handled with the strictest care, and on being released should be let go forward and on no account allowed to fall on one side.

When lambing time arrives it will be found that flocks of about 100 ewes, run in comparatively small paddocks, are most convenient and easily attended. The best feed paddocks available should be utilised at lambing time, and shelter of some description in the paddock is highly desirable. Open, exposed paddocks are most inhospitable to the lambing flock, especially as lambing is usual when cold, wet nights are not uncommon. Once lambing commences the flock should be quietly visited night and morning, care being taken not to disturb the ewes, and for this reason the attendant should not be accompanied by dogs. During these visits many troubles may be alleviated and many lambs saved as a result. In districts where foxes are troublesome poison baits will be found effective if used before any lambs are dropped. Where the paddocks are small sheep bells

round the necks of several of the ewes have a restraining influence on foxes, and an additional safeguard in cleared areas is to set two or three hurricane lanterns attached to stakes driven firmly into the ground in different parts of the paddocks.

Fig. 8.—Suffolk.

Fig. 9.—Shropshire.

Where it is possible it is an advantage to draft off the day or two-day old lambs with their mothers on to better and fresher feed.

Occasionally a ewe, especially with her first lamb, will leave it, and if the lamb is to be reared it must be mothered back to its mother preferably, or to a ewe whose lamb has died. Sometimes this process of mothering requires extreme

patience, but if the lamb is saved it means anything from 10s. or more extra return, so that the time occupied is well paid. Should a ewe lose her lamb it is advisable, if possible, to get her to mother a twin lamb from another ewe.

Fig. 10.—Ryeland.

Fig. 11.—Hampshire.

The most successful way of doing this is to skin the dead lamb and tie the skin so obtained around the less thrifty of the twin lambs and mother it to the mother of the dead lamb.

(c) *Lamb Marking.*

When the lambs are from 10 to 20 days old (and no older), they should be marked, and this is best done in one corner of a well grassed paddock. It is much better practice to mark early, and have two or three batches to mark, than to have some of the lambs too old when the operation is performed. A strip of

Fig. 12.—Carcasses of 15 lambs of even type (College entry for July Export Competition).

temporary fencing and a few stakes will enclose a corner of the paddock conveniently. By adopting a policy of marking on a fresh area of well grassed land, not only is the possibility of deaths from infection of wounds, such as may follow after marking in constantly used sheep yards lessened, but also the risk of lambs being rejected for export on account of caseous lymphadinitis.

The instruments used should be carefully sterilised before and during the operation by dipping them in liquid sheep dip or some other disinfectant such as lysol. A dressing may be applied, and preferably it should be something that will act as a blowfly deterrent; for this mixture one part of Stockholm tar to one part of kerosene is recommended. Actually, if the work is done cleanly no dressing is required on the cuts, but if applied to the wool just close to the cuts the kerosene in the mixture will help considerably to prevent blowfly strikes.

For marking, the flock should be assembled on a mild morning, and driven quietly, and not too far (this applies to after marking as well as before marking), otherwise the lambs get overheated and excessive bleeding will follow. During

Fig. 13.—A crutched ewe.

marking avoid overcrowding, especially of the lambs. The marking should be done early and never later than 4 p.m., as sufficient time must be allowed for the lambs to stop bleeding and mother up before nightfall.

In castrating it is best to cut a large piece off the top of the purse and not to slit it. In cutting off the tail remove at the first or second joint and force the skin back towards the lamb before cutting so that this loose skin will come down and cover up the end of the bone in the tail. If the knife is placed on the tail with the flat of the blade on the skin and the back of the blade towards the lamb the skin can be forced back towards the lamb this way. Then if the end of the tail held in the left hand is bent upwards towards the lamb and over the knife the joint will be easily located (at the bend) and the curve on the outside of the tail will allow of sufficient skin being left to cover the stump when the tail is cut off.

The lambs should always be watched carefully after marking to see that none has been fly blown in the open wounds.

(d) *Feeding.*

Between mating and lambing it is essential not to allow the ewes to become low in condition, and by changing the paddocks weekly, but at the same time

Fig. 14.—A dressed lamb of ideal weight and good conformation.

being careful to reserve a good paddock for lambing, the sheep will do better and the feed will be utilised more economically.

After the lambs have been dropped, if the season is normal, good feed is available. Here again it is better to give the flock weekly changes, never allowing

them to stay in a paddock until it is eaten down very low. It is extremely important that the lambs should continue their growth and at no time receive a check, and to avoid this the mothers must be kept in full milk and paddock feed maintained. This is best accomplished by careful management of the feed available, and regular changing of paddocks. This usually means a change to better feed as well as variation in diet.

Under no circumstances should the lambs be weaned from their mothers until the day they leave the farm for the market.

During the whole year a plentiful supply of clean water and salt lick should be available. A suitable lick is as follows:—Coarse salt 50 parts, superphosphate 25 parts, lime 15 parts, iron sulphate 3 parts, Epsom salts 7 parts. When fresh green feed is present the amount of Epsom salts should be reduced to 4 parts and iron sulphate increased to 6 parts.

Fig. 15.—Lamb and weighing sling.

To go about the production of early fat lambs with the greatest confidence it is essential that a supply of reserve feed be kept on hand for stock in the event of drought and consequent shortage of feed. If feed is present in a conserved form then the risk of the season opening late can be run without worry. Suitable feeds are ensilage and oats and both can be conserved on the farm conveniently. At first the sheep may not take kindly to ensilage, but after a time they will consume 4lbs. to 5lbs. per head daily. An allowance of 6ozs. of oats and 4lbs. to 5lbs. of ensilage per head per day will keep the sheep in healthy tone and condition.

(e) Marketing.

The lambs should be marketed straight from their mothers in as prime and finished condition as possible, showing sappiness and bloom and not a dry appearance.

For the export market the lambs should weigh from 60lbs. to 75lbs. live weight; these will then run from 30lbs. to 38lbs. dressed weight. The ideal lamb for export weighs 32lbs. dressed weight (see Fig. 14). For the local market extra weight receives the attention of the buyer, and with some breeds the lambs can be marketed in better condition and bloom at the heavier weights, so that for the local market lambs weighing 70lbs. to 80lbs. live weight will be found more profitable. Unfinished lambs invariably bring lower prices, and the aim should be to have the lambs well fleshed and rounded off with fat, or, in other words, in prime condition.

In handling the lambs prior to marketing the greatest care should be taken, as they are very liable to be bruised. Avoid poking with sticks, or using dogs which have a habit of biting, and to catch the lamb refrain from catching him by the legs or wool. The best method is to put one hand under and around the

Fig. 16.—Spring balance and lamb being weighed.

neck and to lift the lamb, put the other hand under the brisket just behind the forelegs.

To be sure of the weight of the lambs the most reliable guide is to weigh them, and for this purpose a lamb sling, constructed of a piece of board 19in. x 3in. x 1in. to fit along the belly, and two straps of leather each 48in. long attached about 3in. from the end of the board to form a loop on each side, will be found most convenient (see Fig. 15). The lamb is suspended in this sling and weighed on a clock-face spring balance, as illustrated in Fig. 15.

A daily gain in weight for a lamb varies according to the breed and feed, but $\frac{1}{2}$ lb per day is a general average. At this rate a lamb weighing about 9lbs. or 10lbs. at birth will be about 60lbs. live weight at 14 weeks. Some batches of lambs have reached a live weight of over 70lbs. in 13 weeks.

The loss in weight from the farm to the dressed weight on the hook is generally about 53 to 54 per cent., though in some cases it has been found to be less, according to the distance of travel and the breed.

Where lambs are to be sent by rail and the railway station is some 3 or 4 miles from the farm it is much better to put frames on a hay waggon and transport the lambs to the station rather than to drive them, as driving causes considerable wastage, and the lambs become dry in appearance and lose some of the sappiness and bloom so essential in a quality lamb.

Where lambs are required to travel any distance in a lorry old sheep skins tied around the rails of the frame, with the woolly sides close to the lambs, reduces the risk of bruising to a considerable extent. Some old straw scattered on the floor of the conveyance will usually prevent the lambs from becoming stained and dirty.

On the local market, where the lambs are sold on the hoof, it should be remembered that the more attractive the lambs the greater the attention from the buyers, consequently the greater the competition for them and the higher the price.

Whether sold in London or Adelaide, to be attractive, the lambs must be prime and sappy, evenly graded with regard to type and weight, and be free from bruises or blemishes when dressed.

It will always pay the seller to grade his lambs off into several pens so that each pen contains lambs of even weight and quality. If consigned to the Abattoirs they should be marked on the head with red or blue raddle, so that the agent will have no difficulty in drafting them into their most attractive grouping. Too often the grouping is left entirely to the discretion of the agent and he has to perform the job hurriedly and under the worst conditions, that is, if he has the time to do it at all. After all, the agent can hardly be expected to do this work; in many cases it is not done and a lot of the time and care of the grower is wasted by unattractive or careless marketing.

STOCK AILMENTS.

(An Address to the Ceduna Conference by W. G. Bennett, B.V.Sc., Lecturer on Veterinary Science, &c., Roseworthy College.)

This is a very wide subject, and one can only deal with those conditions commonly met with, and which are capable of simple treatment. Ailments of stock can be roughly divided into three classes, viz., those due to *injury and accident*, the results of which are usually quite obvious and the treatment largely a matter of common sense. The principal points to be observed in all such cases are first of all the removal of any foreign matter which may be present, the cleaning up and keeping clean of any wounds, the application of hot or cold packs to bruises and sprains, and the resting of any animal injured.

The second class, and that with which we are principally concerned, might be called *simple diseases*, which may or may not be associated with germs, but are never contagious. The third class are the *contagious diseases*, such as tuberculosis and strangles.

Dealing with the simple ailments, it can be confidently stated that 85 per cent. of cases met with are directly or indirectly traceable to the bowels, but in every case a proper diagnosis of the condition and its cause should be made before any treatment is adopted. This applies with particular force to the well-known condition of *colic*. All horse owners at some time or another have to deal with cases of this type. Colic is not a disease in itself, but really a symptom which may be due to many quite unrelated causes; actually all it really means is a pain in the abdomen, and may be traceable to an excessive amount of wind in the bowels, an impaction of food there, or, again the actual pain may be in the chest. It is therefore necessary to make a careful examination of each individual case to determine the cause before starting treatment.

To deal with each type separately let us take *flatulent or windy colic* first. This is caused by the fermentation of food in the bowels, with their consequent distention with gas. It is often traceable to succulent foods, particularly when these are damp; but also follows overfeeding with grain, such as wheat, or mouldy fodders. In this form the pain is continuous, and only rarely does the animal throw itself about. It appears afraid to lie down, and is very uneasy with constant pawing of the ground, looking round at the flank, and occasionally squatting like a dog or kneeling on the fore legs to relieve the pressure. This pressure of gas may interfere with the breathing.

Treatment necessarily requires the use of a medicine to relieve the gas, and for this purpose a drench consisting of 1oz. each of turpentine and aromatic spirits of ammonia in 1½ pints of linseed oil will be found most effective. In absence of any other drugs, two tablespoonfuls of baking soda in a pint of water every two hours will be found beneficial. When the pain is severe, and this applies to all forms of colic, a dose of 1oz. of chloral hydrate in half a pint of liquid paraffin (medicinal) is the best drug to use. Do not use laudanum, as it has a depressing effect on bowel action, leading to further constipation. Enemas of warm water and soap should be given at frequent intervals.

The next type is *spasmodic colic*, always traceable to the food, but bad teeth may be a contributing cause. Mouldy food, sudden changes of food, boiled foods fed to animals not used to them are all possible causes.

As a rule the condition develops suddenly; the pain severe; the animal throws itself about, rolls, stretches as if to urinate; kicks at the belly, and looks round at the flank. Owing to the stretching, many people get the erroneous idea that the trouble is located in the bladder (commonly known as "wrong in the water").

LANZ--Bull Dog

Crude Oil Tractors again Available.

New Improved Models.
New Economy Standards.
New Low Prices.
New Sales Policy.

**NEW TRACTORS ARRIVING—All New—but
Traditional LANZ QUALITY Retained.**

LANZ TRACTORS are now made in the following
different sizes :—

- (1). LANZ MINOR, 12/20 h.p.**
- (2). LANZ STANDARD, 15/30 h.p.**
- (3). THE SUPER LANZ, 22/38 h.p.**

A Type Suitable for any Farm.

There is no cheaper way to Farm than with a
LANZ CRUDE OIL TRACTOR.

See them at the Royal Show.

WAYMOUTH MOTOR COMPANY, LIMITED

42 Waymouth Street, ADELAIDE.

SOLE DISTRIBUTORS FOR SOUTH AUSTRALIA.

This is a very rare condition in the horse, and will probably not occur once in a lifetime. Any distention of the bladder is entirely due to a temporary paralysis of that organ, due to the pain, and can frequently be relieved by massage of it through the rectum, or last part of the gut.

For treatment, chloral, as mentioned, will give relief. In its absence $\frac{1}{2}$ pint of whisky or brandy will help. Since it is frequently associated with impaction of the large bowel, soap and water enemas should again be applied, and a drench of 1 ounce of turpentine in $1\frac{1}{2}$ pints of linseed oil will complete the treatment. The horse should be put on a laxative diet for several days after.

A third type of colic, more or less restricted to certain types of country and dry seasons, is *Sand Colic*. Here, although the symptoms are similar to the last in many respects, sand is usually seen in the droppings, and special treatment is required, as well as the general treatment mentioned above. After 12 to 16 hours starvation, give 1lb. of honey in 1 quart of whole milk, followed by the usual purgative. Relief can sometimes be obtained by throwing the horse, rolling it over on its back, and massaging the abdomen. To tone up the bowels, give 1 level teaspoonful of powdered Nux Vomica night and morning, mixed in 1 tablespoonful of treacle. A laxative ration should be fed for a week following, or green feed, if available.

Engorgement with wheat is another fairly common occurrence in horses, and should be treated by giving $\frac{1}{2}$ lb. of baking soda in 1 pint of water every two hours, followed by a drench of 1lb. of Epsom salts and 2 tablespoonfuls of ginger. Watch for founder, and treat accordingly.

Three diseases, due in large measure to feeding, will now be dealt with. The first of these is known as *Lymphangitis*, *Monday Morning Disease*, or *Big Leg*. Certain animals are more prone to it than others, particularly those of a slow lymphatic temperament. It always follows the feeding of a full ration during an extended period of rest, such as the week end; hence the name. Usually both hind legs swell to an enormous size, and are hot and tender to the touch. It may be confined to only one leg, or, in some cases, may also affect the front legs. The animal is off his food, and obviously uncomfortable. The first thing required is a complete clearing of the bowels by the standard drench, and the feeding of a laxative ration. The local condition in the legs is best treated by the application of cold water from a hose or bucket for about 10 minutes twice or three times a day, and gentle massage. The condition may become chronic.

The second is known as *Azoturia*, which is characterised by a sudden paralysis of the hind legs and a coffee-colored urine. It usually follows similar feeding conditions to the last. The symptoms arise suddenly, usually as a stiffness of the limbs, and if the animal is forced to move it falls and cannot rise. Treatment is not very successful, but should take the form mainly of nursing, i.e., plenty of bedding and warm clothing. Turn the animal over at frequent intervals to prevent bedsores. Put on a diet of mash and green feed, give enemas and plenty of cold water. Keep the bowels open with Epsom salts, preferably in the feed.

The third is the well-known condition of *founder*, which usually affects both front feet, occasionally all four. The commonest causes are over-driving, too much hard feed to a stallion, engorgement with cereal grain, too long grazing on growing wheat, and sometimes after foaling in the mare. A characteristic symptom of this ailment is for the horse to stand with both hind legs well under the body, and both fore pushed well out in front, with the weight on the heels. The feet are hot to the touch, and show pain when struck. It is almost always followed by dropped soles. The most effective treatment is to stand the animal in a mud puddle or pool of water for several hours a day, and placing it in a well-bedded stall at night. Water should be run down the legs for several minutes at intervals during the day. Give a 6 dram aloes ball or a dose of oil to hasten the evacuation of the bowels, and place on a laxative diet.

Passing to the dairy cow, the first point which requires stressing is the absolute necessity of supplying a mineral supplement to the feed, irrespective of the ration or pasture to which the animal has access. Owing to the enormous drain on the body minerals by the supplying of milk, many obscure conditions develop in the cow, such as *blindness*, *staggers*, and others which are directly traceable to a lowering of these essentials. This deficiency must be made good, and is better done before the troubles arise. The simplest method of doing this is to add minerals to the ration, and as lime and phosphorus are the two most commonly lacking, a handful of superphosphate added to the feed twice daily will meet most requirements. It is better, however, when possible to feed a complex such as dicalcic phosphate or bonemeal 3 parts, plus salt 2 parts. (Super can be used in place of either of the former, but is not so digestible).

Passing to actual disease conditions, the two of most general occurrence are *mammitis* and *milk fever*. The former is an inflammation of the udder, usually caused by a germ, sometimes contagious, which gives rise to heat in one or more quarters, pain, redness, and the presence of a hard lump. The milk, if any, is watery, containing clots and strings, and will not keep. Treatment consists of the application of hot water fomentals as hot as the hands will stand for 10 minutes, followed by massage of the affected quarters with some liniment, such as camphorated oil. The udder should be stripped out several times a day, and the above treatment applied each time.

Passing to *Milk Fever*, this usually occurs in cows in good condition after an easy calving, and in good producers. After being milked out the animal becomes restless and excited, then lies down in a semi-conscious condition, with the head turned to the flank. The simplest treatment on the farm is to inflate the udder with air by means of a pump, and the animal will usually rise inside a couple of hours. If not, pump her up again. Never drench her while on the ground, but after she gets up a drench of 1oz. each of calcium chloride and ammonium chloride will help to prevent a relapse. Do not strip the cow out for several days after an attack, but just take away sufficient milk to relieve the udder. Always see that the teat tube is well boiled before pumping up the udder. If the teats are tied always use wide tapes.

Bloat is a common ailment of cattle, particularly after eating wet succulent fodder grasses, and can be easily diagnosed by the swelling of the left flank. The administration of $\frac{1}{2}$ lb. of baking soda, or 2ozs. of turpentine in oil, will sometimes relieve the condition, or the passage of a narrow piece of hose into the paunch. When other remedies fail, the flank should be punctured at a point midway between the last rib and the point of the hip, and at the highest point of the swelling. A special instrument, known as a trocar and canula, can be used, but in its absence the gas can be let out by driving in a broad-bladed knife and turning it sideways. The skin should be pulled to one side before making the hole. Turpentine or soda solution can be poured straight into the paunch through the opening.

Bowel conditions similar to those occurring in the horse, and accompanied by pain or "colic," are quite common in dairy cows, traceable to sluggishness of those organs and an impaction of the food mass therein. One condition of almost everyday occurrence is that of a cow losing her appetite and a drop in milk yield from no apparent cause. All such cases respond quite readily to a standard drench of $1\frac{1}{2}$ lbs. of Epsom salts, $\frac{1}{2}$ lb. of treacle, and 2 level tablespoonfuls of ginger in 1 pint of lukewarm water. In fact, it may be said that in all cases of simple ailments in cows the administration of this drench will be attended by excellent results. The treatment should be followed by a course of *nux vomica*, at the rate of 1 level teaspoonful mixed with treacle, and wiped on the tongue twice daily, as a general stimulant.

LANGDON PARSONS' TROPHY.

To the Light's Pass Branch this year belongs the credit—in the person of F. W. Boehm—of winning the coveted trophy presented by Mr. W. Langdon Parsons to the competitor securing the highest number of points over the three years 1931-1932-1933 in the local pruning competition in both the fruit tree and vine sections. The following table sets out the points obtained to each competitor :—

Name.	Branch.	1931.	1932.	1933.	Grand Aggregate.

LICENCES FOR BULLS.

There seems to be a little uncertainty in some quarters about the question of bull licences, chiefly as regards which bulls should be licensed; when, where, and by whom the licence is to be applied for, and how much it will cost.

It might be advisable, in the circumstances, to try to answer these queries now and thus clear up some of the doubts which are in the minds of people who have neither had an opportunity of reading the Dairy Cattle Improvement Act for themselves, nor of having it explained to them.

In the first place it should be noted that bulls located outside of the hundreds of the State need not be licensed at all; the Act applying only to those *within* the hundreds.

Next, it is not necessary to license a bull until after it is six months old, and actually, in some instances, it need not be licensed until it is nearly 12 months old. Nevertheless, owners are advised to give serious thought to the question of licensing immediately the bull reaches the six months' mark.

Here is a simple guide by which one might know when it is time to take out the licence:—

A bull which is over six months old on July 1st (even one day over) should be licensed during July. The licence will cost 10s., and will remain in force until the following June 30th. A fresh licence is required every year in the month of July.

A bull which is not more than six months old on July 1st, but which reaches that age on or before the following January 1st, should be licensed during January. The licence will cost 5s., and will remain in force until the 30th June. Thereafter licences should be applied for every July, and the fee will be 10s. per annum.

Licences are obtainable from local police stations, and from district dairy instructors.

And finally, concerning the question of who it is that should license the bull, the Act states that the responsibility rests with the owner, the part-owner, or lessee, or any person in possession of the bull. This being so, it is always advisable for the owner to see to it that either he or the person having possession of the bull takes out a licence, otherwise one of them, or even both of them, render themselves liable to prosecution.

LIFE — A BUSINESS

It is a paradox, perhaps, that while Home Life is a refuge from business, it is itself a business.

Money enters so largely into everything that it must be planned for in every phase of life.

It is in business that money is earned, in the Home, chiefly, that it is spent, and there is no sound reason why the spending should not be regarded as being just as important as earning. In fact, it is far more important, for earning is difficult and must employ wisdom, forethought, and energy, while spending is easy, so easy that there is temptation to spend unwisely.

Every Home, then, is a business, and needs an economic system, of which the Savings Bank Pass Book can be the valuable basis.

Commonwealth Savings Bank of Australia

GUARANTEED BY THE COMMONWEALTH GOVERNMENT.

SUMMARY OF LIVESTOCK STATISTICS, YEAR 1932.

[W. L. JOHNSTON, Government Statist.]

I. SHEEP AND WOOL.

1. *Number of Sheep*.—The sheep flocks on December 31st, 1932, numbered 7,713,236, constituting a record; the previous highest being 7,646,239 in 1891, and the next highest 7,542,345 in 1927; compared with 1931, 6,608,981, there was an increase of 1,104,255. The flocks were classified as follows:—Ewes, 3,815,513 (3,287,194); wethers, 1,788,094 (1,513,377); rams, 97,858 (86,061); under one year old, 2,011,771 (1,722,349).

2. *Breeds of Sheep*.—86·7 (86·4) per cent. of the flock were returned as pure-bred Merino, and 5·3 (6·3) per cent. Merino Comebacks, 1·0 (1·0) per cent. other pure breeds (Corriedale, Shropshire, Dorset Horn, Lincoln, Romney Marsh, Southdown, Suffolk, &c.), and 7·0 (6·3) per cent. Crossbreds.

3. *Lambing, 1932*.—During the year 1932, 3,127,432 (2,717,101) ewes were mated and 2,270,081 (1,983,667) lambs marked, exceeding the previous year's record. The percentage was 72·59 (73·01).

4. *Winter Lambing, 1933*.—3,264,000 ewes were reported as either mated or intended to be mated for the winter lambing of 1933. In addition, 144,000 ewes were expected to be reserved for spring lambing.

5. *Wool Clip*.—7,573,237 (6,404,046) sheep and lambs were shorn, the total clip including locks, bellies, pieces, &c., being 65,154,632 (56,960,732) lbs., increase 8,193,900lbs. The average weight of fleece for sheep and lambs combined was 8·60 (8·89) and for sheep only 10·42 (10·75) pounds.

6. *Total Wool Production*.—Subject to slight revision, it is estimated that the grand total wool production, including the clip and wool fellmongered and wool on local skins exported, was 75,500,000 (67,021,312) lbs., increase 8,478,688lbs., value £2,302,750 (£1,921,278), increase, £381,472, the average value per lb. greasy being 7·32d. (6·88d.)

II. CATTLE.

1. *Numbers*.—All kinds 312,932 (265,324), increase 47,608. Dairying cattle 149,172 (127,756), increase 21,416, classified as follows:—In milk 101,974 (90,767), dry 29,508 (23,171), and heifers springing 17,690 (13,818). In addition, there were 18,129 (14,896) other heifers one year and over which are possible additions to the dairying herds.

2. *Butter and Cheese*. Provisional for 1932-33. Butter, 21,000,000lbs., and cheese, 6,000,000lbs., both exceeded the previous year's record production of 17,663,029lbs. and 5,096,731lbs., and record quantities were exported—Butter, 9,500,027 (7,400,628) lbs.; cheese, 1,578,780 (908,847) lbs.

III. HORSES.

190,222 (185,222), increase of 5,000.

IV. PIGS.

113,831 (109,780) being the highest since 1917.

V. GOYDER'S LINE OF RAINFALL AND LIVESTOCK.

During the year 1932 the percentage to the total of sheep outside Goyder's line of rainfall increased from 36·12 to 37·72, cattle decreased 28·58 to 28·51, and horses 27·21 to 26·81. The numbers within and without the line for 1932 were—Sheep, 4,803,728 and 2,909,508; cattle, 223,716 and 89,216; horses, 139,231 and 50,991.

VI. INTERSTATE MOVEMENT OF STOCK.

The State gained 46,252 head of cattle, 563,648 sheep, and 2,391 horses by transit of stock between States. The total interstate imports were—Sheep, 629,562; cattle, 52,231; horses, 3,772; and exports sheep, 65,914; cattle, 5,979; and horses, 1,381. Net exports of horses to overseas countries 347.

VII. SLAUGHTERING.

Sheep and lambs, 1,279,245 (1,378,931), including for export 53,355 (135,386); cattle, 88,350 (81,285); pigs, 150,318 (135,822).

VIII. VALUE OF PASTORAL AND DAIRYING INDUSTRIES.

Provisional for 1932-33, £4,800,000 (£4,295,906), increase £504,094.

ENSILAGE COMPETITION—HILLS DISTRICT.

[Judged by Mr. R. HILL, Agricultural Instructor.]

There were 12 entries in the Hills District Ensilage Competition conducted this year under the auspices of the South Australian Advisory Dairy Board. These entries were scattered from Jervois Swamps to Two Wells and were not all ready to judge at the one time, which spread the time of judging over several months. The efforts of competitors in an undertaking, which is quite new to the majority of them, have been very pleasing and satisfactory, demonstrating to many of them the medicinal value of such fodder and many other advantages.

Outside of the ensilage entered for competition, some very half-hearted attempts have been made to cure ensilage, and the resulting failure in many cases has unfortunately caused the practice to be condemned by some, but as a matter of fact the making of ensilage is much more simple than the curing of hay. Weather conditions do not interfere to the same extent with the making of ensilage, and it is an advantage if the material is stacked while wet.

Time of Cutting.—The outstanding fault has been cutting the material too far advanced in growth, or, in other words, after the flowering stage has been reached. The more fibrous a plant is the more difficult it is to exclude air quickly and prevent overheating, which causes charring and an inferior fodder. In the early stages of growth plants contain a higher percentage of mineral matter than the matured plant and have higher laxative qualities so necessary in a suitable fodder for dairy cows, especially in our drier areas. The ease with which young succulent plants can be consolidated and air excluded minimises the anxiety of those who fear overheating, hence the importance of cutting not later than the flowering time of the bulk of the plants included in a mixture should not be overlooked. Young succulent material does not heat very rapidly and the stacking need not be done so hurriedly as is necessary when the material is in an advanced stage of growth. By no means the least important advantage of early cutting is that good growth as a second crop follows, as in the case where the winner of this competition was able to obtain a second cut for hay. During last year Mr. Sparrow, of Sandy Creek, cut wheat for silage as soon as the heads appeared, and the result was that he harvested quite a payable yield of grain for the second growth.

The Economic Point of View.—One continually hears dairy farmers complaining of the costs of concentrates necessary to keep their herds up to a high standard of production, but it is certain that such costs can be, and have been, considerably reduced if their attention is directed to using well cured ensilage in conjunction with hay. At some time of the year excessive growth is found on all localities where dairying is practised, and a lean period follows, but how often is it that full use is made of the material provided in the time of plenty? It is only necessary to pass through the country in the summer months and see the waving fields of dry feed to realise that opportunities to conserve valuable fodder have been lost. Economic grazing necessitates keeping plants growing by delaying their seeding and making full use of the young and more nutritious growth, but the total area on a farm cannot always be handled in this way unless additional livestock is made available during the spring months. The practice on small holdings of buying additional livestock when feed is plentiful and selling when there is a shortage is not sound, and maximum returns can only be had by conserving fodder in its most valuable form as ensilage, hay, &c., and feeding when it is most profitable and not when the farmer is compelled to feed. Some of the inferior annual grasses take control of fields at times if not judiciously

handled, and the cutting of such fields for ensilage before these plants can produce seed minimises the possibility of these plants crowding out the more valuable pasture plants.

Labor Costs.—The labor required to handle bulky, heavy, green material is raised as an objection to the making of ensilage, but this work can be considerably simplified by the use of a tumbler-sweep hoist, which anyone deciding to make ensilage each year cannot afford to be without. This applies, of course, where loose material is to be handled.

Methods of Conserving Ensilage.—In the wet districts, such as the Adelaide hills, where temperatures are low and there is an abundance of tender growth, the stack method is quite satisfactory and the most economical one to adopt, but when it comes to the plain country and northern districts, where cereals are usually the bulk of the material used and hot drying winds play on the open stacks, the trench system is undoubtedly the best. Ensilage has been successfully made in a stack out of cereals at Roseworthy Agricultural College this season, but it necessitated a framework of poles to form a skeleton silo so that sheaves of cereals could be placed parallel to the sides instead of building with butts out as in stacking hay.

The Nutritive Value of Ensilage.—As will be seen from analyses of the various entries in this competition, the starch equivalent is fairly regular, although the mixture of material varies considerably. The starch equivalent averages out at a little under 11 for all entries, and taking standard wheaten hay, which has a starch equivalent of 30.9 as a comparison, it will be understood that one ton of hay has approximately the same feeding value as three tons of ensilage. It must be remembered, however, that a crop which will produce a ton of hay will provide material for approximately three tons of ensilage. The advantage in favor of ensilage is that it is more succulent, has certain laxative qualities, and can be reserved as a fodder almost indefinitely without fear of loss by fire or from vermin. Another point in its favor is that numerous plants which cannot be made into palatable hay can be made of some use in the form of ensilage, although to make first quality silage only the best material should be used.

Moisture.—There was a considerable difference in the percentage of moisture in samples collected, but all have been standardised to 75 per cent. moisture in order to make a comparison.

JUDGE'S COMMENTS ON THE ENTRIES.

1. *D. F. Sheppard*.—Mr. Sheppard's entry was a square stack 12ft. by 12ft., which was 7ft. high when consolidated. Well weighted with stones on completion of stacking. A mixture of subterranean clover, cocksfoot, perennial rye grass, prairie grass, soft brome grass, sterile brome grass, and cape weed cut while quite wet. Cut during the third week in September for ensilage, and the same field was again cut for hay during the third week of November. Very succulent, palatable, and nutritious feed with about 2in. of waste only on the outside. It was the second year that this competitor has made ensilage and he was pleased with the result. He assured me that his cows have shown him the highest returns he has ever had for the time of the year while he was feeding this ensilage.

2. *A. E. Francis*.—The entry submitted was a stack 15ft. by 15ft. covered with 12in. to 15in. of earth. A mixture of subterranean clover, silver grass, soft brome grass, sterile brome grass, perennial rye grass, cape weed, and geranium. Good color, palatable, and quite good nutritive value. Cut when the majority of the cape weed was in flower, which meant that the grasses were young and tender. Feeding to dairy cows commenced on December 29th, and although the feeding of concentrates was discontinued, the supply of milk was maintained, and live-stock was in good healthy condition.

3. *W. J. Dawkins*.—Ensilage was made in an overhead reinforced concrete silo with a capacity of about 100 tons. The sample was taken 8ft. from the top of the silo. A mixture of chaffed malting barley, cape barley, and a few prickly jacks. Very little waste, palatability quite good, but color rather dark. Analysis showed quite good feeding value, and this probably improves further down in the silo where peas come into the mixture. Dairy cows and ewes were being fed from this silo.

3. *R. Enniss*.—The ensilage entered by Mr. Enniss was a square stack 18ft. by 18ft., which settled down to 10ft. when well weighted with logs, but there was about 9in. of waste all around the outside due to the weighting not extending right to the edges. A mixture of subterranean clover, a considerable amount of silver grass, some soft brome grass, sterile brome grass, barley grass, and geranium was collected with a sweep and placed on the stack with a pulley and a grab worked by a horse. Grasses were all a little too much matured, but have cured remarkably well under the circumstances. Readily eaten by livestock and analysis showed really good nutritive value. This was the first attempt by the competitor to make ensilage.

3. *Mrs. A. D. Liebelt*.—The ensilage stack was 18ft. by 12ft. and weighted with stones 1ft. thick. The mixture consisted of clovers, which were principally subterranean, sterile brome grass, soft brome grass, geranium, silver grass, and perennial rye grass. The bottom 3ft. of silage was really good, but the top 3ft., although not waste, was inferior owing to insufficient weight to exclude the air. A fair amount of waste on the western side; the material was a little too mature, which could be overcome in future by cutting at least a fortnight earlier. This is the competitor's second attempt at making ensilage, and it has proved to be satisfactory. The cows receiving it were hanging on to their milk yield well, although they had not had any bran from Christmas time up to the middle of March.

6. *A. Sparrow*.—The ensilage was made in a trench 60ft. long, 12ft. wide at the top and 10ft. at the bottom, and 6ft. deep; covered with about 15in. of soil. A mixture of algerian oats, cape barley, odd plants of Salvation Jane, some barley grass, and sterile brome grass. Cut when the oats were flowering, but the barley was a little too far advanced. Oats predominated throughout and all ensilage was a splendid color, very palatable, and readily taken by the milking cows and other cattle. The percentage of waste was exceptionally small, there being none whatever on the sides and bottom.

7. *W. A. Woolley*.—The stack was 15ft. by 15ft., well weighted with logs, but it had been built too high in the centre, not allowing full pressure of the logs to come on to the outside. A mixture of perennial rye grass, silver grass, subterranean clover, barley grass, and dandelions, all rather too mature by at least a fortnight. There was too much waste on the outside, principally due to the manner in which the stack was built. Quite palatable to livestock, and analysis showed good nutritive value.

7. *W. S. Martin*.—Mr. Martin's stack was built in a trench 60ft. long and 12ft. wide and about 4ft. deep, and above this soil was banked up against the portion built above ground. A mixture of cape barley in sheaves cut at the flowering stage with a considerable amount of barrel clover and burr clover as an undergrowth. After carting was completed, the material was covered with 15in. of soil. There was some waste on top and sides, but the bottom ensilage in the trench was exceptionally good. A deeper trench would be more satisfactory.

9. *R. J. Baker*.—Early Burt oats cut with a binder at the milky stage of the grain comprised the ensilage entered by Mr. Baker; made in a trench 42ft. long with an average width of 10ft. 6in. and 6ft. deep. Bands of the sheaves were cut, but the straws packed in straight, parallel to the sides of the trench. Before covering, the material was built about 4ft. above ground level, and this portion did not have the bands cut. Covered with 18in. of earth it settled down to ground level. Very palatable, a splendid color, and practically no waste. This was the first attempt to make ensilage by this competitor, who was naturally very pleased with his success. Feeding to livestock commenced on January 3rd, and 21 cows and seven poddies were fed until February 21st, and the cows, which were in excellent condition, had kept up their milk supply better than in previous years for that time of the year.

10. *E. Wise*.—The ensilage was made in a stack 25ft. by 15ft., weighted with meadow hay about 6ft. in depth. This was interesting from the point of view that there was practically no waste on the top of the ensilage other than the silage, which was a little inferior, and the bottom portion of the hay had actually become very palatable brown hay. Waste on the outside was about 6in. in thickness with a tendency for the ensilage to be a little inferior inwards for another 6in. A mixture of barley grass, perennial rye grass, subterranean clover, white clover, cocksfoot, prairie grass, cape barley, and lucerne. Although rather dark in color towards the top of the stack, due to insufficient weighting, all the material was quite palatable to livestock and a very valuable reserve of fodder.

11. *V. Lehmann*.—Mr. Lehmann's entry was a round stack 15ft. in diameter, which was weighted with 200 fencing posts. Well consolidated in the centre, but about 15in. of the outside material was inferior silage, probably due to weight not extending far enough out to the edges. Slightly charred, but readily eaten by livestock. This was a very interesting entry, because of the mixture which included barley grass, wheat, poppies, a little lucerne, and a considerable amount of fumitory (pink weed), and prickly jacks. For grazing, some of these inferior plants are never eaten by livestock, but included in this stack as a mixture were readily eaten and helped to make a feed which on analysis showed quite good nutritive value. Another point is that cutting annual weeds at this stage prevents reseeding, which materially helps in cleaning infested fields.

12. *F. O. Ball*.—The ensilage was made in a stack 20ft. by 20ft. square, rather unevenly and lightly weighted with logs. A mixture, principally of grasses, consisting of soft brome grass, sterile brome grass, prairie grass, barley grass, and subterranean clover. The stack was commenced on a base too large for the

quantity of material, and the grasses were all rather too matured, particularly when grasses predominated in the mixture. Although analysis showed the nutritive value to be good, the silage was not very palatable, and there was far too much waste, due to irregular and insufficient weighting for material cut on the late side. Waste does not necessarily mean absolutely useless material, but includes inferior silage that will be eaten by livestock, and has been charred by excessive heat, developed because the air has not been excluded quickly enough.

NAMES OF PLANTS INCLUDED IN THIS REPORT.

Salvation Jane (*Echium Plantagineum*); prickly jacks (*Emex australis*); barley grass (*Hordeum murinum*); sterile brome grass (*Bromus villosus*); soft brome grass (*Bromus hordeaceus*); subterranean clover (*Trifolium subterraneum*); cape weed (*Cryptostemma calendulaceum*); perennial rye grass (*Lolium perenne*); prairie grass (*Bromus unioloides*); silver grass (*Festuca myuros*); geranium (*Erodium botrys*); barrel clover (*Medicago tribuloides*); burr clover (*Medicago denticulata*); fumitory (*Fumaria muralis*); white clover (*Trifolium repens*); cocksfoot (*Dactylis glomerata*).

STINKWORT POISONING.

Reply supplied by Mr. R. H. F. Macindoe, B.Sc., M.R.C.V.S., to a question, "Treatment for sheep suffering from stinkwort poisoning," submitted at the Upper North Conference.

So far as has been determined by feeding tests, stinkwort itself contains no poisonous principle, but stinkwort eaten at the flowering stage, especially if damp, has been associated with heavy mortalities in sheep, due to the flower specules (awns) damaging the lining of the bowels and allowing the toxins of a germ to penetrate.

The germ responsible, *Bacillus oritoxicus*, is found in soils, &c., and is taken in with the food eaten. If animals are constipated, the action of the poison is increased.

Treatment.—As affected sheep are usually found dead, or if seen alive, live only for a few hours, no medicinal treatment is effective, but steps should be taken to prevent the appearance of the disease by—

1. Keeping sheep off stinkwort when in the flowering stage and when damp.
2. Preventing constipation by giving licks containing Epsom salts or by placing Epsom salts in the drinking water.

A suitable lick would be:—

Superphosphate	50lbs.
Slaked lime	124lbs.
Common salt	40lbs.
Epsom salts	10lbs.
Molasses	5lbs.

To Make.—Mix the super and lime thoroughly, breaking down all lumps. Then mix in the common salt and Epsom salts and moisten with the molasses (mixed with water). As the disease is a bacterial one, experiments in preventing the disease have been successfully carried out by using a vaccine for the purpose, but this is only indicated for use on those properties where the disease occurs regularly every year, as the disease may frequently make its appearance on a property only once or twice, after which no further cases occur, and the expense of vaccine treatment may not be justified.

ORCHARD NOTES FOR SOUTHERN DISTRICTS FOR AUGUST.

[By CHAS. H. BEAUMONT, District Horticultural Instructor, &c.]

Pruning will have been completed, all cuttings burned, and big cuttings protected with a coat of white lead paint.

Winter washings or sprayings for prevention of fungous pests should be carried out this month; there is no doubt of its usefulness in preventing curl leaf and shothole, and it helps materially in controlling scab in apples and pears. Anthracnose in vines is controlled by swabbing with a 10 per cent. solution of sulphuric acid, or with the sulphate of iron mixture; vines should be scraped clean before swabbing to get best results.

Brown rot in citrus is dealt with by spraying with Bordeaux mixture and by destroying diseased fruits. The use of the copper solution may also stop the skin disease known as *Xanthema* by adding a small proportion of copper to the soil. Peach aphid is controlled to a great extent by early spraying with red oil or black leaf 40.

The most important work is to get the soil into good working order. Trees cannot function properly in sodden soil; it must be in such condition that the air can circulate freely, and thus keep bacterial activity continuous. Soil in good condition is warmer than a sodden soil and trees can do better.

Strawberry beds need clean cultivation and good drainage.

Do not keep any sickly plants in tomato houses; it is much safer to lift them out and burn them and replace with a strong plant.

If it is intended to use fertilisers, do it now and dig them in deep.

Currants may safely be said to be out of hand now, after another prolonged drying season, which has clearly demonstrated the usefulness of dehydrators. See that every scrap of waste fruit is disposed of and not allowed to be a harbor for fruit moth.

These notes will be the final from my pen. The monthly notes have necessarily been short, but they have brought me many letters of inquiry, and many words of appreciation, for which I am very thankful.

I have always urged thoroughness in orchard and vineyard work. I know how much there is to do, and how few hands to do it, but there is reason in advocating thoroughness because it decreases work.

When planting new trees get good ones from a reliable nursery and plant early, because early planting has been proved to be the best.

However well you may spray to control codling moth, you are not going to get good results if shelters are left for the larvae.

You can spray to prevent fungous diseases, but unless you clean up diseased fruits early and often, you are simply making the work continuous.

Mixing several spray materials together may seem to save work, but it is a dangerous practice and not reliable.

Good cultivation (with drainage) takes time and needs good implements, but it results in healthy trees, and only healthy trees can give good quality fruit.

I have advocated co-operation as the best means of getting a good pack and good prices, and feel sure that this will come in the near future.

The new season has opened well from a production point of view, and I trust that growers may have many successful years before them.

“WATTLE” Binder Twine

MADE IN SOUTH AUSTRALIA.

“Good Twine Saves Time.”

Farmers who insist upon a **QUALITY Twine** (keeping one eye on economy) should order “Wattle” brand this season.

“Wattle” brand has established a reputation for quality. Its unusual strength ensures freedom from breakages, it runs freely and evenly, thereby saving time and money.

“WATTLE” BINDER TWINE

UPPER NORTHERN BRANCHES, MORCHARD, JULY 19th, 1933.

EFFICIENCY ON THE FARM.

[By A. McCALLUM, Morchard.]

Farm efficiency is applied methodical common sense in the running and management of the farm.

It is, no doubt, a very easy matter to find the faulty or inefficient methods of neighbors, but to put the finger on our own is the thing that we must try to do, and this is one of the objects of the Agricultural Bureau.

Firstly dealing with machinery, many farmers are too busy or hard pushed for time ever to read the instruction book. Careful study of the instruction book will pay very big dividends in the life of a machine.

With internal combustion engines, use only the best oil and greases, for when a farmer has to pay several hundreds of pounds for a machine, it is worth while to put that little difference in price between poor and good lubrication into that machine, for in all cases good lubrication pays.

See that the fuel—whether for car, engine, or tractor—is strained. This, in the long run, will prove a time saver. One may go perhaps for months without trouble through not straining the fuel, and then perhaps, miss an important engagement, or lose several hours with blocked fuel pipes.

Always clean gauze strainers at certain periods, for even with the best strainers sediments get through.

When emptying oil tins or drums, be careful of the last drop, for it is usually in this that the water and rubbish collects, and unless strained may ruin expensive bearings.

Keep your eyes and ears open, and if you see or hear something wrong, stop and remedy it unless it is trivial, even then it pays, for “a stitch in time saves nine,” and nothing is surer than that adage when applied to fast moving machinery.

When feeding cows, pigs, horses, &c., always have the feeding utensils in a convenient place.

Do not leave implements in a far corner of the farm; they may be needed later, and time will be lost in getting any parts or tools that are required.

Take care of any borrowed article and do not forget to return it in the stipulated time or when finished with. It is easier done then than when in the middle of an important job.

Efficiency can be practised in many other ways on the farm, and these are only a few which I have noted. There are many others, and they will all prove time and labor saving.

THE FARM ORCHARD.

[By P. J. CURNOW, Wirrabara.]

Every farm where locality and soil conditions will permit, should possess a small orchard. The annual production of even a moderate quantity of clean, fresh fruit means a saving, and the satisfaction of growing the home requirements is an added incentive. A farm home, surrounded by even a small number of fruit, shelter, and other trees, is more attractive than the usually bare farm buildings to be found in country districts.

[Papers Read at Conferences.]

In the dry northern areas, too often the conditions are such that the planting of fruit and other trees has proved unprofitable and a waste of time and effort. The principal factors against success, are long dry summers, unsuitability of soil, the absence of any irrigation system, and too often failure on the part of the owner to give his trees reasonable care and attention.

THE SITE.

Many homesteads are situated on high ground. Generally there is a hard, marly subsoil beneath the surface of the surrounding soil. To attempt to plant such land with fruit trees—particularly if the situation faces the hot north—is to court failure. If then a suitable site for a farm orchard is to be selected, the prospective planter should try to select a piece of good, sandy loam over a red clay that is not too retentive. The site if possible should face south or east, and sloping land is best. These conditions, the writer is aware, are often difficult to obtain, but, he affirms, are ideal for the purpose.

CULTIVATION AND PLANTING.

Having selected the orchard site, proceed to break up the soil to the greatest possible depth, with a big team. An old, heavy single furrow plough makes the best job. If this work is carried out before the fence is erected, the whole area can be broken up. If the soil is left in a state of fallow from one winter to the next before planting is carried out, fruit trees will thrive better than if put into the fresh, rough soil. After securely fencing against stock and vermin, proceed to lay out the rows. The first row should be not less than 20ft. from the fence. This distance permits of the easy turning of the team when cultivating.

Trees should be planted not less than 20ft. apart. At this spacing 100 trees to the acre can be planted. After marking out the places for the trees—either on the square or diagonal system—proceed to dig the holes. Each should be 3ft. to 4ft. square. Throw on one side the loamy surface soil. Clean out the hole to the depth of a long digging fork. Proceed to break up the bottom soil to the greatest possible depth, care being taken to keep the subsoil in the bottom.

As the surface soil is being replaced, break the sides of the hole down, thus preventing the formation of a tank-like hole, which would prevent the natural spread of the roots. Before planting each tree, roots that are too long, and others that are broken, should be cut back.

The roots should be spread out in the prepared hole in a natural manner. Care must be taken to plant the tree a little lower than it stood in the nursery row; when the soil settles, the height will be right. Tread around the tree carefully, firming the soil. If the weather is dry at planting time, give a can of water.

The best time to plant fruit trees in the north is June. Late July and August planting, particularly in the drier districts, too often means either failure, or poor success. It must be remembered that fruit trees, in common with most other trees, start into growth in their root systems some weeks before any top growth becomes apparent.

The above conditions constitute a somewhat ideal state of affairs in laying out a farm orchard, where a choice of selection of a site can be made. Too often a farmer tries to surround his home with fruit and other trees under less favorable circumstances. An exposed site, a hard retentive clay, or worse still, either marl or limestone, have to be dealt with. If the site is too exposed to hot winds in summer and cold driving rain storms in winter, any attempt at fruit growing under such conditions should be abandoned. On the other hand, if a comparatively sheltered site can be selected—even where the subsoil is as above described, something can be done, that will help win success.

The use of explosives in the Wirrabara district in the preparation of land for planting out commercial orchards has been adopted with considerable success. Much limestone country has been planted to stone fruits where the holes have been blown

[Papers Read at Conferences.]

out with agricultural dynamite and the subsoil broken up to 3ft. in depth. Fruit trees so planted have stood up to the past five years of drought in a remarkable manner. If land of a similar type found around some farm homesteads were treated in like manner—even using two plugs of explosives to each hole—success would attend the planting of fruit trees of a suitable type, and the expense would not be prohibitive.

VARIETIES.

The selection of the right varieties of trees is important. Unless the locality selected as an orchard site is well sheltered and the soil of a good loamy character, with a deep clay subsoil, the planting of apple trees is not recommended. A 20-inch rainfall is essential. Where conditions are right, the Jonathan is the best summer apple, followed by the Cleopatra for winter eating. Where the locality suits, Rome Beauty may be tried. A selection from these keeping culinary varieties may be made:—Stone Pippin, Dunn's Favorite, and Granny Smith. For late keeping, Rokewood and Tasma are recommended.

Stone fruits are more suited to poorer soils and drier conditions. For early peaches Brigg's and Wiggins are best; to be followed by Peregrine. For preserving, Elberta and Goodman's Choice may be selected.

Japanese plums are more suited to moister conditions. Climax, Santa Rosa, Rubeo (a blood variety), and Wickson are best.

In apricots, Oullin's Early is the first early; Newcastle Early is not recommended. It produces too many small fruits. Tilton and Moorpark are preserving and drying varieties. European plums are harder than the Jap. varieties. These could be tried. For early kinds:—Early New Orleans, Angelina Burdett. Medium season:—Coe's Golden Drop, Greengage, and Kirks. In late varieties:—Monarch, Grand Duke, and President.

In nectarines only one variety is recommended—Goldmine.

The pear tree is hardier than any other pip fruit, and will thrive under comparatively harsh conditions. A good subsoil, though, is essential. A tree or two of Duchess will be sufficient to supply a home. While an excellent dessert and preserving variety, it is a poor keeper. Packham's Triumph is a good dessert kind, and is specially recommended. Other good varieties are Josephine, Glou Morceau, Vicar of Winkfield, and Kieffer's Hybrid. The latter is a hardy variety. Cherries are not recommended for the north, except in sheltered and hilly districts, where there is a good rainfall.

Where irrigation, even on a moderate scale, is available in summer orange trees may be successfully grown, even on plain country, where the soil is suitable and heavy winter frosts are not experienced. It is surprising to note the excellent growth such trees make in many small northern gardens, and the crops of really good fruit that are gathered. The orange tree, well planted and given a good soaking every four to six weeks, will often thrive where other fruits either fail, or are a poor success. These kinds are particularly recommended:—The Navel, St. Michael, Parramatta, Valencia Late, and Joppa.

A few fig trees in a small orchard give a crop of fruit annually, even when other varieties fail. The white kinds are best.

Half a dozen kinds of grapes are not too many. Early varieties are Crystal and Sweetwater. Later kinds are Grand Turk, Lady's Finger, Malaga Red, Muscatel, and (for jam making) Wortley Hall. A few trellised Zante currants will provide a home in currants for a whole year. Cincturing or ringing is necessary, or the crop will not set.

The above varieties of fruit trees can be recommended, and will give good returns where conditions are reasonably suitable. In long periods of drought fruit trees, in common with all vegetation, must suffer severely in even comparatively good districts. With the idea of keeping those who may wish to replant old areas or lay out new orchards, there points are submitted.

[Papers Read at Conferences.]

THE USE OF PRODUCER GAS FOR FARM TRACTORS AND MOTOR TRUCKS.

[By L. M. W. JUDELL, Jamestown.]

Although producer gas has been used for heating, power generation, and other industrial purposes for the past hundred years, first in Europe and later in almost every country in the world, its use as a fuel for farm tractors has naturally been quite a modern development. In South Australia, as well as in the other States of the Commonwealth, the fall in price of wheat and other products of the soil during the past four years—with the consequent necessity for farmers to lower their costs of production—has led to some interest being taken in this cheap fuel for power purposes on wheat farms.

In a paper given by the writer at a Conference of the Upper North Branches of the Bureau at Black Rock last year, the nature and methods of generation and the requirements for power purposes of producer gas were dealt with in some detail. In order to avoid going over the same ground, in this paper it is proposed to give a short resumé of the use of producer gas for farm tractors and motor transport, and to summarise the advantages and disadvantages inherent in its utilisation.

It is obvious that the cost of the fuel for farm tractors is only one item in the schedule of costs, but it is a large item and offers an opportunity to the farmer of saving a substantial amount each year on the purchase of petrol, kerosene, and oil. At the present time many farmers in various parts of this State owe, in some cases, hundreds of pounds for liquid fuel which has been used in their tractors, a state of affairs to be deplored. The advantages from a national point of view of using charcoal made from wood grown in our own country as compared with the importation of expensive liquid fuel from overseas is very apparent.

THE NEW MODEL DOMO

AWARDED THREE PRIZES AT THE ROYAL SHOW, ADELAIDE, 1932

ARRIVED !!

SKIMMING BOWL, semigyroscopic.
BOWL SPINDLE, with improved conveyor.
NECK BEARING, with spiral spring cushion.
GEARING, new Automatic type. No springs or pins to handle.
OIL SUMP protected against milk or water.
SPEED INDICATOR.
FRAME beautifully enamelled, and
TINWARE heavily tinned.
Bigger sizes fitted with BALL-BEARING SPINDLE, eliminating neck bearing and reducing OILING TO ONCE A YEAR.

[Papers Read at Conferences.]

In the report of the Advisory Council of Science and Industry of South Australia, 1930, it is stated:—

The Committee has no hesitation in saying that it can see no practical difficulty in the adoption of the charcoal gas producer lorry for a substantial proportion of our country road haulage. The producer is of such simple construction that there is no reason to anticipate any greater cost for repairs and depreciation than with a petrol-driven lorry, and there should be no difficulty in training a driver of an internal combustion engine to successfully drive a producer gas lorry.

The investigations of this Committee were confined to the use of this gas with motor lorries up to the time at which this report was issued, but it will be seen that the members found no reason to alter their opinions when they extended their researches into the problem of using producer gas with farm tractors. The same report is thus concluded:—

The economic benefits which South Australia would derive from expending money in labor in preparing wood and charcoal for use in such lorries and tractors, instead of sending the money out of Australia for liquid fuels must be obvious."

In 1928 the Federal Commission of Development and Migration deputed a sub-committee to investigate the possibilities of the use of producer gas for motor transport purposes. This Committee, after collecting and studying the results and experience of French and Belgian engineers and users of this gas for the same purpose, carried out trials in Victoria with satisfactory results. Their work has been chiefly confined to the application of producer gas fuel to heavy motor vehicles, and is fully reported in their publications. I quote the following extract from the 1928 report of this Committee:—

If, by the use of a cheaper fuel, the cost per ton mile were reduced by only 1d., a national saving of £304,260 would result, enriching primary and secondary producers to that extent, or expressed in other terms, placing them in a better position for meeting overseas competition.

Going on to discuss the effects on the Forestry Industry and the utilisation of waste forest products it is said in the same report:—

This amount of waste timber converted into charcoal would provide 850,000 tons per annum which at £2 per ton would be worth £1,700,000 to the saw-milling industry.

The same Committee of highly qualified experts concludes:—

The sub committee, as a result of its investigations to date and information obtained relating to the use of producer gas as a motor transport fuel, considers that the use of this type of fuel offers definite promise of effecting important economic savings in Australia, and further, of enabling material now having no commercial outlet to be used advantageously to the general benefit of the Commonwealth.

The *Bulletin*, in an article discussing the efficiency or lack of efficiency of some of our Australian industries, says:—

The one small sign of progress or attempted progress is in connection with the use of producer gas (from charcoal) for tractor purposes, and that has perhaps one millionth the attention which Test Cricket has commanded during the past six months.

This rather exaggerated and somewhat cynical statement I do not endorse, but it serves to show that the subject being dealt with was regarded as being of considerable national importance.

OTHER REPORTS.

Turning from the general aspect of the proposition to more specific cases, I would briefly refer to the report of an official trial conducted at the Hawkesbury Agricultural College, New South Wales, last year, written by the Director of Agriculture of that

State. Two Fordson four-wheeled tractors of the usual design were run side by side: one on producer gas and the other on kerosene. Each pulled a four-furrow disc plough, equivalent to a six-horse job. The comparison of the salient points was as follows:—

	Gas.	Kerosene.
Speed	2.56 miles per hour	2.8 miles per hour
Area	2 acres in 2 hours 30min.	2 acres in 2 hours 16 min.
	.8 acres per hour	.88 acres per hour
Fuel	24lbs. charcoal per acre	2½galls. kerosene per acre
	1gall. water per acre	

The Director states:—

The charcoal gas driven tractor created a very favorable impression and gives promise of being the means by which farmers can utilise cheap fuel. (Charcoal is quoted by him at 50s. per ton.)

Similar successful work has been done on farms in all the States, as I learn from reports in newspapers and technical journals sent me from time to time.

IN SOUTH AUSTRALIA.

Coming closer to home and reporting the results of my own observations, I refer to the very successful work done by Messrs. J. I. and W. F. Slattery on their farms at Belalie East and Canowie, near Jamestown, using 2-ton Holt tractors and producer gas generated from charcoal in gas producers designed by Mr. J. I. Slattery. The State Committee, above referred to, appointed by the Minister of Agriculture, conducted a trial with a unit outfit, consisting of a Holt tractor, Slattery producer, and 17-hoe combine on Messrs. Slattery Bros.' farm at Belalie East, and I shall quote a few extracts from their report:—

Inspector Longstaff's report shows that during 3 hours 4min. of engine running time, of which 2 hours 45min. was actual working time, 44lbs. charcoal and one-third pint of petrol were used, the total cost being 1s. The area cultivated was 12 acres, so that fuel costs were 1d. per acre. Water consumption was 2galls. per hour.

ALL USERS of SUPERPHOSPHATE

Are cordially invited to the Lounge Room of

at the service of visiting Farmers, and Interesting
Exhibits have been arranged.

IMPORTANT : Ask for your Notebook. There is one for every
bona-fide User of Superphosphate.

[Papers Read at Conferences.]

The committee desires to emphasise the importance of the Government assisting in every possible way the development of producer gas power for farm tractors. It is difficult to over-estimate the importance of this to South Australia. Mr. Slaterry informed the committee that it cost him and his brother between £500 and £600 a year for liquid fuel and lubricating oil for three tractors, and he was confident he could reduce this outlay to about £200 by the use of charcoal gas.

The committee would again urge upon the Government the advisableness of encouraging the development of producer gas-propelled vehicles by reducing to a nominal amount the annual registration fee on such vehicles. Not only will the general adoption of producer gas power as applied to mechanical transport (and tractors) result in a very large reduction of tractor farming costs, but it will provide employment for a considerable number of men in preparing wood and charcoal. Further, it will retain in the State many thousands of pounds now expended on power fuels.

The members of this committee are highly qualified engineers, chemists, and executive officers. It may be added here that Messrs. Slaterry Bros. have consistently used producer gas with their tractors for the past eighteen months on their farms, and have cultivated and tilled about 5,000 acres in that time. It will be noted that I have throughout quoted the reports and opinions of highly qualified and disinterested experts, members of committees appointed to investigate the use of producer gas and others. This has been done, not in an endeavor to build up a particularly strong case in favor of the producer gas fuel, but in order to give the facts of the case.

On Eyre Peninsula producer gas is being used to some extent by farmers and motor vehicle users. Mr. W. H. Brownrigg, Agricultural Instructor, has kindly supplied me with some interesting information on this subject. He states:—

Mr. J. V. Evans, of Parabba, is getting almost ideal results from this fuel (producer gas), used in a 2-ton Holt tractor, having gone over 1,000 acres without any trouble. Mr. Evans pays great attention to the scrubbers, as he considers that this is the most important part of the plant. The tractor had very little trouble to pull a 20-tine combine over newly burned scrub land.

A Wallis (wheel type) tractor pulling an 8-furrow plough, following, has been covering 10 acres to the bag of charcoal, using petrol only to start; the lubricating oil has to be changed after three weeks' use and is still fairly good. The tractor was also used at harvest time to pull a large stripper, and the danger from fire was not considered serious. A Holt 15 tractor worked by a farmer here with charcoal gas pulled a mallee combine over 1,100 acres at a total cost for fuel and oil of £22 11s. 2d.; the oil consumption was unduly heavy.

Mr. Brownrigg also describes the running of an old Ford truck, carting wheat, using producer gas; it ran 2,820 miles on 12½galls. petrol and 2,820lbs. charcoal—a fuel cost of about ¾d. per mile.

Recent reports from Streaky Bay district indicate that a local maker is making and fitting gas producers to tractors, trucks, and motor cars (even sedan cars) which give most efficient and economical service on charcoal fuel.

After having submitted the foregoing information which would tend to prove that producer gas can be used as an economical and efficient fuel for tractor, truck, and car engines, the question naturally arises why it has not come into more general use in this country and why there have been a number of users who have tried it and abandoned the attempt. Among the several reasons for these disappointments is, I think, the fact that the farmer, generally speaking, is used to working comparatively simple, positively operated implements and machines which are to a large extent standardised and are adjusted ready for use. This is no reflection on the intelligence or initiative of farmers who are not supposed to be engineers or mechanics. The gas producer certainly adds to the complication of the tractor outfit, which alone can give sufficient mechanical troubles at times; the fuel must be generated in the gas producer continuously and uniformly as used, and the efficient making of the gas and its correct admixture with air is a process which requires some degree of skill and experience which will be attained much quicker by some men than by others who

[Papers Read at Conferences.]

perhaps do not possess the mechanical aptitude. The farmer pioneering this process, new to him, has no skilled teachers or advisers, but has generally to pick up the new technique as best he can. The cost of the gas producer, freight, and alterations to his tractor engine, about £60 to £70, is also a deterrent in these times of financial stringency. It is often deliberated on, and the result is a decision to play safe and spend the money on more kerosene. The use of the gas is certainly not as convenient and efficient as is the use of liquid fuel, for which the tractor engine was designed, so naturally and perhaps wisely the tractor owner hesitates before he embarks on the use of this new fuel. It must, however, be remembered that one cannot have it both ways: some sacrifice of convenience and comfort must be made in order to be able to work the land for a penny per acre for fuel cost.

I have viewed with misgivings the supplanting of horse teams on farms by tractors, and do not think it has been for the welfare of the farmer generally. It is not safe, however, to regard the advent of the tractor on the farm as a passing phase and in districts where the average rainfall is low and subject to irregular and often disastrous fluctuations, causing failure of crops through droughts, the right type of tractor using this very cheap and locally produced fuel can be profitably used for farm purposes by men who possess mechanical aptitude and who will persevere in learning the correct technique and management of the gas producer and engine. The cheap fuel allows of the unrestricted use of the tilling implements to work the soil, which practice is so necessary in a dry climate, and the expense of purchasing or providing fodder for the horse teams in times of drought is obviated.

MURRAY LANDS WEST BRANCHES, KAROONDA, AUGUST 3rd, 1933.

**THE CARE OF CREAM FROM THE COW TO THE FACTORY, AND
INCIDENTALLY, THE CAUSE OF SO MUCH SECOND GRADE BUTTER
IN SOUTH AUSTRALIA.**

[R. ELLIOT, Kulkawirra.]

The main point in the handling of milk and cream is careful cleanliness, there is nothing that will taint quicker than cream or butter, and it is not only necessary to keep everything connected with them absolutely clean, but also to keep them right out of contact with any foreign odour. This is often the cause of trouble on farms where only a small quantity of cream is produced, and where there are not all the necessary requirements for the care of cream, many people are doing their best to turn out a good article under very adverse circumstances, especially in newly settled areas. Some people are careless, but they are in the minority.

The main cause of the large quantity of second-grade butter is in the large number of small suppliers of cream, and their being scattered over a very wide area of country, and the fact of their having to keep the cream too long before sending to the factory, through having some distance to bring their cream to the railway station. Then the cream very often has to stand on the station overnight, and until the train goes the next day, with the lid of the can close shut. Nothing deteriorates cream more quickly than to be shut up in that way. To test this, shut a can of cream up tight for one night, then take off the lid and take a whiff of the air from the can. The only way to combat this difficulty is to have cream depots on railway stations of any considerable size, where there would be some one whose duty would be to see that all cans containing cream had the lids raised to allow of the circulation of air. It would be necessary that these depots be dustproof, and to give the best results they would need to be artificially cooled in summer. There would also need to be a cool compartment on the train, because cream travels very long distances on trains, and cannot do otherwise than become heated on the journey in hot weather.

[Papers Read at Conferences.]

There is another factor which must not be overlooked in the forwarding of cream; the container must be clean and sound, there must be no rust patches or places where the tinning is off the can. In Victoria, such cans would be condemned by an inspector, and their use prohibited.

No butter maker can make good butter from bad or tainted cream, and the fact that so much of South Australia's cream is produced as a farm sideline over such a scattered area is the main cause of so much second grade butter.

CONCRETE ON THE FARM.

[W. TRESTRAIL, Coomandook.]

It should be the aim of every good farmer to make substantial improvements on his farm from time to time as finances permit. It is true that in these days of limited incomes and small returns, we can do little to accomplish our aims and ideals. In most districts a good deal of natural material is available in the form of sand and limestone for the making of permanent improvements on the farm, such as the house, sheds, barns, concrete fencing posts, and other improvements. Most of the main buildings can be erected with masonry work that will fill the bill, but in the case of floors in out-buildings, verandahs, tanks, &c., concrete is the ideal.

Every task on the farm can be more easily and pleasurably carried out where concrete has been employed in the construction of the buildings, floors, and surrounding yard areas. Indeed, a temptation exists to wander around the farm generally and make a careful record of how much of the daily labor that is now somewhat fruitlessly expended in repeated endeavors to "clean up" and keep things in order, could perhaps be eliminated by replacing many farm structures with permanent concrete floors, walls, and even roofs.

Modern experience of building in all its phases, and in every variety of climatic conditions, indicates that, for the construction of every possible requirement of the farm having the nature of permanent fixtures, concrete will prove to be not merely an expenditure, but a capital investment, ever gaining in value along with the natural market price of a well improved farm.

LIME CONCRETE.

Lime concrete can be used in floors where not much weight will be carried, or in walls that can be cement coated and that are not vitally important.

With lime concrete it will be necessary to burn or procure the lime. This can be done on most farms where limestone and mallee roots or wood are available. Dig a kiln 6ft. deep and about 6ft. in diameter. At the bottom of the kiln dig a trench about 1ft. deep and 1ft. wide across the kiln. Then dig down a lighting opening on the west side say about 5ft. x 2ft. and 7ft. deep, and make a tunnel through from the kiln to the opening, which should connect the trench at the bottom with the opening which should be about a foot or two from the kiln. Place dry kindling wood and leaves in the trench right into the secondary opening to facilitate lighting the kiln. Place about 18in. of solid mallee roots or wood in the bottom of the kiln, then about 8in. of limestone cracked to about 4in. or 5in. lumps. Continue with alternate layers of wood and stone right up to the top. A larger amount can be placed above the surface, and this will burn down during the process of burning. Place an extra amount of fuel on top of the lot. If possible set the kiln alight in calm and dry weather. When the kiln has got well alight—say in about 10 to 15 minutes—throw in dirt to block the opening from the lighting opening to cut off the draught. Let the kiln burn itself out, and in 48 hours the lime will be ready to use.

The lime must be "slacked" by placing in a tub or other suitable container and about 8galls. of water used for every bushel of lime "slacked." Judgment must be used in doing this, depending on the quality of the lime used.

[Papers Read at Conferences.]

To make the work as easy as possible, a mixing board helps considerably. The mixing board should measure 8ft. x 8ft. and be supported by jarrah joists 3ft. x 2ft. apart upon which Baltic flooring boards are mounted. Failing this, select a nice smooth hard place as near to the work as possible and do the mixing of concrete thereon. Have all materials handy to save labor and time. The materials wanted for the job are good clean, coarse sand; rain water, if available, is best; cracked stone, according to the job to be done; cement or lime.

CEMENT CONCRETE.

If a floor is to be put down, the following will serve as a guide. If the floor is for a cowshed or where heavy weights are to be carried, it will need to be at least 5ins. or 6ins. thick and should be all cement concrete. A good formula is three parts sand, four parts cracked stone, and one part cement. Do not guess at quantities, but have some definite measure, such as a petrol tin, if it is a small job; or if a bigger job, a properly constructed box with handles that can be used by two men. Place the required quantity of clean, coarse sand on the board, then measure the cement and mix these two ingredients thoroughly until the color is uniform. Pebbles or broken stone are measured in the same way, spread on top, and the mixing process repeated until the color is again uniform. Open out the whole mixture in the form of a big ring. Add water slowly in the depression in the centre of the pile and mix well until the desired consistency is obtained—a jelly-like consistency. Do not use too much water. See that the place where the concrete is to be placed is thoroughly wet, and place the concrete in position as quickly as possible. It should be placed in "blocks" say 5ft. wide or square, a section at a time. This should be thoroughly tamped down so that the material is worked into a tight mass, thus expelling any air pockets that may have formed. Smooth off and leave for 24 hours, and then over the top apply a coat of three parts sand and 1 part cement to the thickness of $\frac{1}{2}$ in. Dust with neat cement and trowel over with a smoothing trowel. This work should be allowed to dry slowly, and covered with wet sacks for a number of days. The setting or hardening of cement is a chemical process which happens naturally, as well under water as in air. The process takes place slowly, and water is an essential factor in it, consequently the water used for mixing the concrete must be kept from evaporating or drying as long as possible. This is usually achieved by covering newly made concrete for about 10 days with not less than 2ins. of wet sand, earth, old bags, grass, straw, or other materials which will afford equally good protection. This is essential to prevent the rapid evaporation of the water mixed within the concrete compound, due to the action of the sun or wind.

The making of concrete in frosty weather should, if possible, be avoided. Freezing causes expansion of the water within the as yet soft concrete, preventing the correct bonding of the different layers, and often causing thin scales to peel off the surface, and sometimes in severe weather even a disruption of the concrete mass.

If the floor is for a shed where not much weight is to be carried, say, a chaffshed or a front verandah, a lime concrete can be made up of 3 parts stone, 3 parts sand, formed into a ring or bay, the lime slacked in the centre and mixed to the required consistency. This is placed the same way as cement concrete, and when it has been in place 24 hours and well tamped, spread over the top a coat of 3 parts good clean, coarse sand and 1 part cement, and when this has been done, sprinkle over with neat cement and trowel over and smooth off.

Another method if the floor is a deep one—as in a verandah wall that has to be filled up to the correct level—is to fill the bottom part with sand or earth and leave for some time until it has been well trodden or tamped down and then crack about 4in. of metal on the top and tamp well. Mix the cement of 3 parts sand and 1 cement very thinly so that it can be poured into the stone. Do this in 5ft. sections and finish off as mentioned before.

[Papers Read at Conferences.]

Corroded iron tanks that are badly out of repair can be made as good as ever again by using cement, sand, and wire netting. The following method will be found useful:—The tank must be thoroughly cleaned of all mud and foreign matter, both inside and out. Holes are punched in the walls. These holes should be approximately $\frac{1}{4}$ in. in diameter and spread about 12 ins. apart. Small mesh wire-netting of lin. mesh x 22 gauge is then lapped around the tank both inside and outside, the layer for the bottom overlapping the walls about 6 ins., both layers being laced through the holes, using fine wire. In the case of large tanks, the bottom must be cemented first, overlapping the walls about 6 ins. and allowing to harden to provide a foothold when plastering the walls. Before plastering, the tank is treated with a neat cement wash thrown on the surface by means of a brush. This is to provide a bond between the tank and the plaster. Mix a mortar of 3 parts fine clean sand and 1 part cement with only enough water to provide a workable mix. Apply in the thickness of $\frac{1}{2}$ an inch. When almost hard, scour the surface to provide a bond for the next coat. Allow each coat to harden, then apply damp cure for two days. Thoroughly moisten each coat before application of succeeding coat. Cure finished work seven days before using. The finished tank combines a neat appearance with strength and utility.

If fencing posts to be made from concrete are thought of, I advise a reference to Mr. Spafford's Bulletin No. 225, "Cement Concrete Posts for Fencing."

POINTS TO BE OBSERVED IN HANDLING AND MILKING COWS ON A MALLEE FARM.

[G. R. TREGILGAS, Yurgo.]

Owing to the unparalleled period of low prices offered for cereals, the wheatgrower has to investigate other sources of revenue to eke out an existence, and the cow has definitely proved itself to be one of the best servants on the farm. It has also been proved that from a few cows a weekly or fortnightly pay can be received throughout the greater part of the year. When a farmer decides to go in for cows, there are quite a number of essentials to be observed and adhered to to make the venture a profitable one. They are as follows:—(1) Kindness; (2) cleanliness, (3) feeding; (4) proper seating; (5) good milking; and (6) breaking in heifers.

Kindness.—Always bear in mind, a dumb animal loves kindness. When handling a cow or breaking in a heifer, handle her gently and quietly, and when proceeding to milk at all times speak to her. An occasional stroke or two anywhere on the body gives a cow confidence.

Cleanliness.—Whatever number of cows are kept, they should be tied up in their stalls, and before milking, all teats and the lower portion of the udder should be washed. If there are more than two cows to each milker, a spare bucket or tin which contains water should be provided, so that the hands can be washed before starting to milk the third cow. Stalls should be cleaned out daily and so arranged that urine will drain away immediately.

Feeding.—Whatever the time of the year, always feed cows at milking time, even when there is plenty of good green paddock feed. A cow will always relish a little chaff and bran and oats, and she is always more contented while being milked. When the paddock feed is going off, start to increase the bran or oat and chaff ration, bearing in mind that however well fed, the average cow will show a profit, and if it happens to be a cow that will not do so, then get rid of her. If one has a small paddock of good ground close to the homestead, try and grow a patch of lucerne or any summer fodder—the cows will always pay for it.

Proper Seating.—Proper seating is the first essential to good milking. Select the most convenient type of seat, and for this I prefer the three-legged stool and not a box or petrod tin as is often seen in too many cowyards. They are not handy, are

[Papers Read at Conferences.]

too cumbersome, and always collect dirt and filth. The stool should be a comfortable height to make milking a comfortable job. Good seating means comfort, ease, and quickness in milking.

Milking.—It is well to note that all cows are not alike to milk, therefore it is necessary to study the flow or delivery of milk in all quarters of the udder. There is no hard and fast rule as to which quarters should be milked first—it should be left to the common sense of the milker. It is best to combine that which will be the most convenient for the milker to operate and that which will give the quickest relief to the cow; therefore, it will be found that in some cases it is best to milk the front quarters first, while in others it would be best to milk the hind quarters. I advocate the method that will give the quickest relief to the cow, because with every cow there is a certain amount of strain on the muscles of the lower part of the stomach. This is to counteract the swing and pull motion of the milker; a motion that should be eliminated as much as possible. Some milkers have a most unnecessary habit of too much pulling and swinging. Milk with the full hand, avoiding as much as possible the finger and thumb method. Some cows are much better than others to milk, and however good a cow is to milk, it is an easy matter to spoil her with too much of the finger and thumb method, commonly called "stripping." Most cows need a little stripping when finishing off. Some cows can be milked efficiently and quicker by the full hand method from start to finish, and it is best to cultivate that method—quick time in milking is a big factor in the comfort of the cow. Always milk as quickly as possible and create a good froth on the milk; this usually denotes a good milker. Having a froth on the milk often enables the milker to keep the milk clean; for instance, should any dirty matter, such as manure or anything else which may be on the cow, fall into the bucket, it can be picked out of the froth without touching the milk. Without a froth, a milker may stick his fingers in the milk and lose the dirty matter, which immediately commences to dissolve in the milk. There should be one good milker in the family, so that he or she can educate the other members. It is essential that a beginner should be educated, because the many points of advantage in connection with good milking can be much more quickly taught than if they are left to be found out. Should there not be a good milker on the farm, then one member of the family should visit the nearest farm where there is an experienced milker and obtain a few lessons.

Breaking in Heifers.—Some people favor tying the heifer to a post if they have not a bail, and when she is thoroughly quietened do away with the rope and milk her anywhere. Almost any herd of cows can be trained to be milked anywhere, but that system has its disadvantages, because at times a cow may have a sore teat or flies be troublesome, causing the cows to fidget and move about; then the milker loses time following her about. Also, some cows eat more quickly than others; they then go and disturb and horn other cows. To avoid all that trouble a stall should be provided for each cow and every cow tied up. Have one bail only, and that for breaking in, particularly if the heifer is unruly; but if not, tie her up in a stall. Do not make a practice of using a legrope when breaking in; almost any heifer can be broken in without it, especially farm-bred heifers. This can easily be done by the following method:—Sit close in to or under her with the knee or lower portion of the thigh against her leg and your head against the upper part of the flank; a cow never kicks without first giving a warning. The milker can feel that warning the instant it is given. Immediately parry or ward off the intended kick with the left arm, and if she continues to kick viciously, grab the off-side hock with the left hand. The cow will then be powerless to act and will soon give in, providing she is not treated unkindly.

Always be punctual with milking times, and do not forget that kindness means confidence. "Cleanliness is next to Godliness." Proper seating means a saving of milk, time and defence against kicking. Feeding means better financial results, and good milking practically covers the lot.

[Papers Read at Conferences.]

POULTRY.

[E. PAPE, Wynarka.]

First, select the ground for the buildings on a nice, sandy spot, and build a shed the following size:—60ft. long by 15ft. wide, 6ft. 6in. at the back, 8ft. high at the front, with a lean-to roof; leave a space at the back the whole length of the building about 8ins. wide, and cover with wire-netting, then divide the shed in the centre, making two houses 30 x 15. Let the shed face east or north-east; the front should have 2ft. of galvanised iron at the bottom and the remainder wire-netting. When the shed is finished put a wire-netting yard at the front of the houses 60ft. x 60ft. Divide in the centre, which will give two houses and runs that will accommodate a flock of 300 birds as layers. Allow the birds to have the use of the runs until about 10 a.m.; provide free range over the farm until feeding time, say about 5 o'clock, and then give the evening feed inside the runs. When all the birds are inside, close the gates for the night and then all are safe for the night from foxes. Next, two houses will be required for runs for the breeders. Put up two iron houses, 10ft. x 6ft., open front, with wire netting runs 30ft. x 10ft., and each house and run will accommodate 12 hens and cockerel in each yard, which should keep the supply of pullets up to the 300 mark. The idea for these houses is to save expenses in losses by foxes. When fowls are perched in the trees and implement sheds, many are taken by foxes; a farmer loses more money in a year by foxes than will cover the cost of the fowl sheds.

SELECTION OF STOCK.

The most popular breed is the White Leghorn. This breed is used extensively by commercial poultry farmers throughout Australia.

Type of Birds to choose for Breeding Stock.—Hens: Go to one of the most reliable breeders who can supply second-year hens that lay eggs over 2ozs., and select the following as they are at liberty on the floor:—Good, big birds of fine bone; birds that stand well up from the ground, legs set well forward on the body, which should be a good length; eye bright and bold, back long and straight as possible from neck hackle to tail; comb and wattles of medium size and very fine texture, and comb evenly serrated. Pick up and handle the birds, pick out the one with a good long breastbone and good width between the pelvic bones. These hens, to my mind, should breed first-class birds. The cockerel to mate with these hens should be of good size, good length of back, a good flow of feather, good, well serrated comb of spikes, firm and straight, free from thumb marks and side sprigs, good, almond-shaped lobes, tail carried at a nice angle—not straight up—and bred from a hen that laid not less than 250 eggs as a pullet. A pen of this description should give a good foundation. Every year pick out the best laying pullets and reserve for breeders, taking particular care the eggs are not less than 2½ozs. in weight.

Heavy Breeds.—Australorps are the most popular breed up to date, with Rhode Island Reds coming into favor. When selecting a breeding pen of Australorps or Black Orpingtons, buy a few good second-year hens of a well-known strain. They should have good big body, legs fairly short and a good distance apart. Eyes black, beak short and thick, comb short and velvety, back short from neck to tail. Mate with a cockerel short and deep body, bright red comb, well serrated, eyes black, tail nice and short, amid long sickle feathers. Cockerel and hens should be a good beetle-green, not purple. This class of bird should breed first-class layers, but always bear in mind and only breed for the eggs over 2ozs.

Rhode Island Reds.—This breed is going ahead with leaps and bounds. In the last few weeks, on visiting a few of the largest poultry farms in the city, the demand for Rhode Island Reds is bigger than the supply. They are a good table bird and can be bred to lay as many eggs as any other breed. They lay a good sized egg of a nice brown color.

[Papers Read at Conferences.]

MATING.

To mate a pen, get a few good hens—not pullets—of good size, say about 8lbs. in weight, good length of body, full, low chest, not cut away from beak to thighs, and rather inclined to be square-bodied; and color, dark brick red as pullets. It does not matter if the feathers are faded in the old birds, but see that the breast feathers are dark red, the under-color to be red to the skin with a small portion of smutty color for breeding only, which helps to keep that nice glossy red in the pullets. Mate to a good upstanding cockerel about 8lbs. or 9lbs. in weight; nice, evenly serrated comb of medium size, good dark-red eye—a necessity in the hens also—a bright red color, all one shade, free from smut, and a nice black tail, not bronze color.

If I find a bird off color I pen up away from the rest of the birds, give one day's grace, and if not better without treatment in 24 hours, I kill the bird and burn it. At the time of writing this paper—July 23rd—egg merchants are quoting 6d. per dozen for ordinary eggs, infertiles higher. At the same date the New South Wales Egg Board is paying 1s. 6d. per dozen, less 1d. levy. We have a good association—the Red Comb Association—in this State, consisting of about 1,700 members, and I think an Egg Board should be formed in South Australia on similar lines as the New South Wales Board.

EASTERN EYRE'S PENINSULA BRANCHES, COWELL, AUGUST 10th, 1933.

MIXED FARMING.

[FRANK MASTERS, Roberts and Verran.]

This is recognised as the day of the specialist—the man with one aim, devoting his whole time, energy, and costs to achieve the best and highest that points the way and goes furthest.

But all cannot be specialists, either from inclination or ability, or the financial position of one may preclude the necessary expense.

In the agricultural history of South Australia we recall the work of such men as Marshall in wheat, and Murray in Merino wool, among others in the same and other directions who by their specialisation have largely benefited the mixed farming industry of the State. Roseworthy College, too, has supplemented private efforts and enabled producers to grow more wheat per acre, more wool per sheep, more butter per cow, and more eggs per hen, which, in these days of stress, are factors which must be practised to enable farmers to live and carry on.

In other words, specialisation in mixed farming has become a real necessity for the agriculturist. With low prices for all production of the farm, the above points will enable us to reduce losses or increase profits as the only way out.

I regard mixed farming as an insurance for successful operation. A lifelong experience in the farming vocation has shown me that never until the present have all prices of produce been down to the lowest together, but usually either wheat, wool, butter, eggs, pigs, or lambs have been higher in value than the depressed commodity, and has enabled the mixed farmer to pull through, whereas with wheat alone, and many of the others singly, disaster would have been inevitable.

By mixed farming practice the waste of the farm in offal, weeds, &c., can be controlled, eliminated, and turned into profit. Cases in point are the farm flock grazing partially at least on weeds encouraged by cultivation, the dairy herd grazing similarly and supplemented by storage of ensilage from the abundant winter growth, and pigs partially grazing weeds, supplemented by offal otherwise unsaleable.

Without these waste savers, the majority of farms would be unprofitable, even with good prices. No waste can be permitted to-day, and only the mixed farmer can make the best of this opportunity of converting the waste into saleable produce.

[Papers Read at Conferences.]

With fluctuating values for various products, mixed farming alone offers the agriculturist the opportunity of conversion into more payable products—those products which may be unremunerative when sold directly.

In this case wheat, oats, barley, and hay at low prices may be fed to animals and poultry on the farm and better returns secured. Too often we forget we have an advantage in doing this on the farm, instead of allowing the feeding specialist to do so, in the fact that expense of bags, partial cost of freight, &c., contributes towards the profitable conversion, together with the feeding specialist's profit.

Mixed farming widens the horizon of interests and one can find in it that variety which becomes the spice of life. Change from the humdrum of one thing brings recreation and relaxation that means invigoration of body, mind, and spirit. The watching, helping, and encouraging of the natural laws of breeding, feeding to secure higher and better growth and production, becomes an absorption once one tastes the fruits of success therein. Always ahead and before the enticing possibility of growing better wheat, better wool, better sheep, better lambs, better pigs, and poultry is the triumph which makes effort worth while.

FACTORS ESSENTIAL IN MIXED FARMING.

These are judgment, management, feeding, and marketing. Judgment really is included in the whole four and makes or mars the whole. It may be termed initial and incidental, and initially is concerned with securing the start or successful inauguration of mixed farming. In this district finance is usually the governing factor. Judgment demands purchasing the best, but here the settler on new country is limited to the funds at his disposal. Aim not at quantity, but quality. In Merino sheep, cast for age shed ewes form one of the best judgments of an initial character when they can be obtained, and followed up by purchases of good rams, the operator may quickly possess a flock of sheep of excellent quality.

He then has in his possession good groundwork for combining fat lamb production by introducing good Southdown rams upon a portion of that flock, or a Border-Leicester ram on portion, selling the male lambs for export and retaining the ewe lambs to be used as mothers for fat lambs for export. Faulty judgment would only have given this man a secondary product of lower value and hard to sell.

Pedigrees of stock are fully protected by herd societies and stock associations, and proper Governmental authenticated tests can be relied upon by the producer, so that in them he has an excellent guide for selecting initial and subsequent stock, and if he cannot for any reason purchase the best at the outset, he can, through the above records, be sure of buying later stock that will improve those he possesses, according to his judgment and pocket.

The process of improvement of quality will be slower, and for most will be the one followed. Management, however, must be on sound lines.

In wheat, starting with good varieties suited to the district, continual care is necessary regarding cultivation, manuring, harvesting, &c., so that the best sample is produced. Bad management means deterioration of returns and price. The admixture of foreign grains, notably barley, must eventually reduce its value.

Whilst the crossbred animal appears to be the ideal for meat purposes, yet the nondescript crossbreeding resulting in mongrels without type or character must be avoided. The fat jowelled pig must disappear from farms, being displaced by the longer, leaner, and small headed pig, with the Large White predominating in crossing, but the Tamworth-Mid York mother seems the ideal, with the Large White sire. Produce what our customers require and get away from anything of our own fancy. This is true of all production, but notably true regarding the pig.

More judgment is required in managing cows. The weighing and testing of milk is the only certain way of finding out the boarder. Here again the registration of bulls gives an excellent avenue to secure increased quality in the herd. Combination

[Papers Read at Conferences.]

in a locality of a number of farmers would make it easy to secure excellent blood of cattle and horses in the purchase from time to time of good sires. It has been said that half the breed is in the feed, and here a few suggestions are offered. Understock rather than overstock, but adequate stocking is necessary. Research has shown short grass to be the best, and here the moving of sheep frequently and grazing each paddock quickly, will prove beneficial.

All stock must be kept growing, any setback or stunting means loss of quality and increased cost to restore that quality, which indeed is not always possible, therefore reserves of fodder in the form of hay, straw, cocky chaff, silage, or grains such as oats and barley are necessary.

Once a farm is properly fenced, every effort should be made to carry the most stock possible, consistent with proper results, thus making the return for improvement greater.

Regarding the question of marketing, much remains to be done in the way of organisation. The individual selling of production without due consideration of effect on prices appears to be a question which needs mature consideration. The bulking of consignments of given quality of lines of production may give confidence to customers, and for such lines increased prices should result. The aggregation of our production at overseas ports is essential in many lines for direct shipments. This is notably the case regarding lambs, pigs, butter, and eggs at Port Lincoln, where there are all requirements for processing and handling. In this case it is worthy of notice that last season's Port Lincoln lambs secured the highest average price for the State, but it was regrettable that double the number were not marketed that way, which means increasing the values of stock remaining and preventing the local market from being glutted with the surplus which should have been exported. The main thing is to export our surplus and the sooner this is recognised the better.

The mixed farm should be conducted from the standpoint of realising the highest returns to the owner and the foregoing will contribute to that end.

So convinced am I of the necessity of mixed farming that I am inclined to propound the axiom "The farm which is not a mixed farm is no farm at all." In the same way a farm without permanent supplies of water cannot be considered a farm, but both are essentials.

CONSERVATION OF FODDER.

[C. F. JERICHO, Butler.]

During seasons of periodical drought farmers turn their attention to the all important question of fodder storage. A large number of farmers do not give this important matter due consideration from a business point of view. While seasons are bountiful they are apt to forget the bitter lessons learned in drought years, instead of conserving a reserve of fodder for lean years which will come again. An important operation of farm activities should be the conservation of fodders of some description. On Eyre's Peninsula farmers have been advised to have a side line such as dairy cows. Many farmers have adopted this side line in the last two good seasons, but after a few good seasons lean years will follow, and unless those farmers who have adopted dairying make preparation for the ensuing years, they will be in a sad position with their cows if they have to buy feed at £7 a ton.

Hay conservation does not appear to be the most successful, because of mice. Every farmer should make large stacks of straw in good seasons which will last for many years without getting damaged by weather or mice, and in time of drought can be chaffed, and should the farmer have to buy oats, bran, and molasses to mix with it, it would be much cheaper than to purchase hay chaff at about £7 a ton.

[Papers Read at Conferences.]

The best method of storing feed for dairy cows in good years is to make ensilage. It can be made out of any green fodder that grows on the farm. Very often in wet years the hay crops are full of barley grass and are not fit to cut for hay; this kind of crop is best to cut just as the grass is coming out in head. It can be turned into ensilage and will make good summer feed for dairy cows or sheep. It can be stored in stacks or pits, will last for years, and no mice can damage it. I have fed ensilage for two years to cows all through summer and have found there is no other feed to equal it for milk production. Oats, wheat, or barley make the best of ensilage, but anything else on the farm, very often not fit to cut for hay and turned into ensilage, makes good feed.

BREEDING MERINO SHEEP.

[R. P. SMITH, Miltalie.]

Breeding plays a very important part in returns for the producer's labor, and the purpose of this paper is to outline a few points for the benefit of those who have not had much experience in this branch of agriculture.

BREEDING.

Find out the class of sheep best suited to the district—fine, medium, or strong. Take note of established farmers and see which has done best with them. Medium wool sheep will be found suitable for most agricultural districts. Having settled the desired type do not change unless for a good reason; never try and follow fashion; this means the breeder as well as the class of wool grown.

Many flocks are ruined and much money wasted because farmers insist on changing the blood, in other words, their breeder. It is only possible to fix a type and keep it by following a definite blood line. One "fixed type" of sheep makes classing at shearing time much easier, and gives better results.

Constitution is the first essential; no flock is worth spending time with if it has not got a good constitution. Constitution comprises a good frame, big bone, plenty of width between the eyes, and a good, broad nose. In the sire, look for a masculine head with heavy horns, carried well away from face and not too close at base. The chest should be deep and broad, giving plenty of lung room, feet strong and straight, big, broad teeth, but not too long, legs set well apart, ribs well sprung, not too much flank or many lambs will be lost while young, because this makes it difficult for the young lamb to find teats.

Both rams and ewes should have clean, soft faces, free from harshness, with eyes, eyelids, nose, lips, and tongue as free from black spots as possible. Sheep showing much black on these points are likely to leave black, or partly black, lambs.

The ears should be short, thick, and covered with a soft velvety covering and the neck in as straight line as possible with the back; a dip either before or behind the withers is objectionable, if before it indicates a weak constitution.

Look for a level top line. In rams the horns should be evenly marked; if a strong wool sheep big corrugations in the horn; if fine wool sheep small corrugations. If the marks on a ram's horn do not correspond with his wool, he will not give good results because he is of mixed type.

WOOL.

The wool should not vary too much between the shoulder, sides, back, breech, or belly; the more even the wool the less pieces at shearing time and more fleece wool.

Farmers should not try to put too much wool on their sheep. Get weight of wool with length of staple instead of growing short, tight wool; remember that it is not possible to have the maximum of density and length on the same sheep. Too tight a wool means wrinkly sheep and "fan tails" and no end of trouble with the blowfly.

[Papers Read at Conferences.]

An open woolled sheep always does better than a wrinkly sheep, and the air penetrates the open fleece and makes wool a better color.

Try and breed true Merino wool with a pronounced crimp, even all over, and watch for substance in the wool; put your hand on the sheep's back and see what resistance the wool gives, the more resistance, the more substance, providing it is not heavy in grease.

Too much grease is very objectionable; it makes the wool low yielding, gives poor price per pound, overloads the sheep, and is the forerunner of bad constitution. In summer in dusty districts it is the means of collecting much dirt, because it usually is a hot day on a dusty day; the grease is then dissolved and collects the dust. Do not try and grow a heavy fleece, but have as much as possible of what you do grow. Substance and crimp will keep out the dirt if anything will.

Open the wool and while open run a finger through the opening to see how many cross fibres it has. If many cross fibres are found, that wool is "noily," which helps to spoil the yield.

Aim for a bright wool with plenty of crimp, one that opens freely. Woolbuyers want a sound, high yielding, bright wool. Some countries have imposed an import duty; that of France is, or was, about 1s. per pound. If one man breeds a 33 per cent. yield, another 53 per cent. yield, which can the buyer pay the most for? Less import duty and less freight, &c., on the latter. The five essentials in wool are substance, evenness, crimp, color, and yield.

SOME HINTS ON THE CARE OF SHEEP.

[W. G. SMITH, Miltalie.]

This is a subject which seems to be neglected at Bureau meetings and Conferences, more particularly on this side of the Gulf. Eyre's Peninsula will never come into its own until wheatgrowers generally of this great Peninsula take up sheep more seriously and the facilities necessary for the successful carrying of flocks. There is probably nothing on the farm that will show over a period of time a better net return than sheep, providing they are run under proper management.

There are no animals that respond more readily to care and attention or show a greater profit for the value of the food consumed. They will eat a greater variety of vegetation than any other domestic animal, goats excepted, but at the same time they are most fussy about feed and water should it be rank in any way, fouled, or tainted; therefore be careful to see that there is plenty of clean water situated as centrally as possible. See that the drinking troughs are kept clean and do not run more than about 350 grown sheep in one flock in the winter months; twice this number may be run in one flock when the feed is dry, because they do not travel over the paddocks so much and at the same time dry feed does not foul like the green feed paddock.

SHEARING.

There are many sheep shorn four to six weeks earlier than necessary. This is a matter that each individual has to decide for himself, taking into consideration the circumstances of the case, watching the safety of his sheep and wool with flies and grass seeds.

Take those cases where shearing could be delayed one month with safety. That is to say, the grower is getting one-twelfth more of the clip in the woolpack, which is grown under the best conditions of the year; whereas if that month's wool goes out on the sheep's back for the year, it is exposed more or less to dust, weather conditions, and grass seeds, which are an economic loss on the following wool clip. Such early shorn sheep are at a considerable disadvantage throughout the year; in summer they

[Papers Read at Conferences.]

are encumbered with that one month's extra wool; in winter, which is a critical time, such early shorn sheep have to carry not only an unnecessary amount of wool, but moisture. This is very hard on lambing ewes should autumn rains be late, as in the past season, when in the hills district over 2½ in. of rain fell in May in 14 recordings. This meant that approximately for half the month the fleece of the sheep was more or less heavy with moisture.

Apart from the advantages already mentioned in favor of shearing in season, it can be carried out with much more ease when the feed has hardened in spring; then sheep can be off the feed for a longer period without harm, the shed is cleaner, the days longer, there is more yolk in the wool, and the sheep shear better.

LAMBING.

The best time of the year to lamb is a very important question. There are quite a number of points to be considered. The April-May lambs should, in a run of years have the best chance. If earlier, they are likely to get a bad start and it is hard on the ewes. Lambs of this age have a better chance than younger lambs to go through the following summer. They are more out of the way at shearing time and at a suitable age to shear and wean, cutting more wool, worth more per pound. Shear as near as possible each year to the same time.

Do not have the ewes lambing any time of the year. If a ewe rears one good lamb a year and cuts a good fleece of wool she has done well. If there are young lambs coming along all the year round, it means that the lambs' wool will be a variety of lengths. It would be an advantage if flockowners timed their flocks to lamb at about the same time; such management would not give the fox such an advantage.

When lamb marking, do the job as quickly as possible and get the sheep back into the paddock. If an instrument is used for ear marking, the same is generally suitable for putting a small notch in the ear as an age mark. This method will be found very convenient in drafting, culling, and working with sheep in various ways.

When drafting sheep through the yards, much invisible harm can be done by allowing sheep to crush through gates, more particularly off shears. When legging sheep, do not drag the animal out with its leg pulled up in an unnatural position; this is likely to cause lameness. Do not hang on to a sheep by the wool; this is cruel. Skin the next sheep you do this to, and you will be convinced.

DAIRYING IN THE DISTRICT.

[J. S. JACOBS, Miltalie.]

It always pays to keep a few cows on the farm, even though local producers are isolated as regards a market, and only receive small returns for their labor. Further, there is only one boat per week by which to send cream to the factory. This means that great care must be taken of the produce or it will market second grade cream, which means another cut in the returns, which are already small enough.

Do not have more cows than can be properly fed and cared for. As this district is subject to long, dry spells, without any or very little green feed, five or six cows well looked after will return more money in the year than nine or 10 left to get what they can pick up in the paddocks.

The Milking Shorthorn strain is one of the best for our trying conditions. They are very quiet and contented and easy to fatten in spring when feed is good. Although perhaps not great butter producers, the cows keep in milk through very hard times. It is also necessary to dry them off before they come in again.

There is also another good point about the Shorthorns, one has not long to keep the bull calves if not wanted for bulls. At 16 or 18 months old a beast will weigh about 600 lbs. for the butcher.

[Papers Read at Conferences.]

Another important point is to obtain the services of a pure bred bull, and even if the cows are not first-class there will soon be enough heifers to replace them.

As regards feeding, oats grow well in this district and are one of the best feeds for cream. If fed with a little chaff, cows do well on them.

GAS PRODUCERS ON TRACTORS.

[MESSRS. R. F. MAYFIELD AND J. E. BEINKE, of Kelly Branch.]

[Read by Mr. Mayfield.]

In these times of low prices for wheat and relatively high costs for power and equipment of production, farmers must of necessity search everywhere for means of lowering costs. The increase in the price of tractor fuel during the past eight or 10 years has been rapid and has at last reached that state where substitutes for kerosene and petrol are being eagerly sought after. Many farmers have laid their tractors aside and gone back to horses, but the price of this means of power has risen much beyond its economic value when compared with wheat.

Up to the present charcoal gas producers have come nearest to reducing production costs. The mallee farmer can burn his own charcoal and thus turn mallee stumps, which are pulled up from his land in the course of cultivation, from a liability into an asset.

The preparation of the charcoal is of the utmost importance. It should be well burnt, but not overburnt, and when taken from the pit should be broken into lumps not bigger than a pint pannican and thoroughly screened. Clean charcoal is probably the greatest factor in securing satisfactory results from a producer.

[Papers Read at Conferences.]

To prepare charcoal from mallee roots the best method is to sink a hole in the ground about 3ft. 6in. deep, 5ft. in width, and 12ft. in length. Seven 7ft. sheets of 24 gauge iron are required for a covering. To burn the charcoal first light a fire in the bottom of the pit and feed it until there is sufficient fire to cover the bottom of the pit. Then slowly fill up the pit, allowing the fire to keep burning freely until the top is reached. When the fire is burning all over and the stumps well alight, cover with sheets of iron and put loose dirt on all joints to make them gas tight. Along each side at intervals of about 3ft. leave openings or flues for the smoke to escape and allow the material to gradually smoulder until the stumps have all turned to charcoal. These openings must be regulated in size according to the fire. The iron covering should never get too hot for one to put his hand on it. The pit will burn about 15 to 18 hours, according to how fast or how slow the fire burns before closing it down completely. One can tell when the pit is ready to smother by the color of the gas which emanates from the flues. The charcoal should cool off sufficiently in from 48 to 72 hours to allow of its being removed from the pit with safety.

I have a 28-50 tractor and a producer attached and have been using this combination for about 11 months. I did not have the high pressure pistons put in the engine, but have continued to work the tractor as it was. It still has 12 of its original rings after going over more than 9,000 acres of ground and doing several weeks of other work besides. I am able to pull a 14-furrow plough or a 24-row combine or a 10ft. harvester over undulating country at 2½ miles per hour. In her present state, the tractor develops 2,000lbs. on the drawbar in top gear and 3,000lbs. in low gear. If the engine was rebored and high pressure pistons fitted the tractor's present power would be increased by 35 per cent.

Mr. E. J. Beinke has a 18-32 tractor and a gas producer attached. The engine has been rebored and high pressure pistons fitted. On this plant a very small quantity of kerosene is introduced to the cylinders with the gas with very satisfactory results. Mr. Beinke considers that his tractor is developing 90 per cent. of its original power on this mixture. His power plant handles a 20-row combine comfortably. In tests to compare costs, Mr. Beinke used 25galls. of kerosene to combine 45 acres, and with the gas and kerosene combined he used 5galls. of kerosene on 48 acres—a saving of 20galls. in a day's work.

Mr. Beinke has combined about 430 acres and ploughed about 90 acres. He has added about 2galls. during that time, whereas had he been using kerosene he would have used 21galls. of oil at 7s. 6d. per gallon, or an amount of £7 17s. 6d., and when allowing for the 2galls. added represents a saving of £7 2s. 6d. Pulling a 9-furrow plough while fallowing 90 acres the saving was £3 in oil alone, or 8d. per acre. Under ordinary circumstances, the tractor would have used 150galls. of kerosene to do this work, and with the gas it has used barely one drum, about 40galls.

The varying conditions of the soil control the consumption of fuel. The land this year is very hard indeed, and this is all in favor of kerosene in these tests. Even now the gas producer shows a saving of 2s. 8d. per acre against kerosene.

The actual cost of fuel, apart from charcoal, was 8½d. per acre. In ploughing 200 acres the only fuel used to supplement the charcoal was 10galls. of petrol, which cost £1. This represents a cost of 10 acres for 1s. or 1½d. per acre. The oiling system on the tractor is force feed and the oil is only used once, so that there is no saving in cylinder oil on this tractor; only it can be drawn off from the final gears fit to use on farm implements. I used 12galls. of oil to plough 200 acres, which cost £4 10s. or 5½d. per acre, making a total cost, apart from charcoal, of 6½d. per acre.

Both Mr. Beinke and I are satisfied that there is not the wear on the tractor while using charcoal gas that there is when working with kerosene. The charcoal gas is much softer in its action than kerosene, and consequently the life of the pistons, rings, cylinders, and bearings is greatly increased. Keep the charcoal dry—wet or damp charcoal in a producer gives poor results.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

EYRE'S PENINSULA.

The Branches of the Agricultural Bureau on the eastern side of Eyre's Peninsula held their Conference at Cowell on August 10th under the auspices of the Miltalie Branch. The Branches represented were Butler, Kelly, Yadnarie, Mangalo, Roberts and Verran, Miltalie, Elbow Hill, Mangalo Women's, and Balumbah Women's. Mr. J. P. Story (Elbow Hill) presided, and the Conference was opened by Mr. A. L. McEwin (Advisory Board of Agriculture). The Department of Agriculture was represented by Messrs. W. J. Spafford (Deputy Director of Agriculture), H. B. Barlow (Chief Dairy Instructor), H. D. Adams (Agricultural Instructor), and H. C. Pritchard (General Secretary).

The following papers were read:—"Conservation of Fodder" (Mr. C. F. Jerich., Butler); "Mixed Farming" (Mr. F. Masters, Roberts and Verran); "Dairying in the District" (Mr. J. S. Jacobs, Miltalie); "Gas Producers on Tractors" (Messrs. R. F. Mayfield and J. E. Beinke, Kelly); "Breeding Merino Sheep" (Mr. R. T. Smith, Cowell); "Some Hints on the Care of Sheep" (Mr. W. G. Smith, Miltalie).

A number of questions were discussed and replies given by Department Officers. The following resolutions were carried:—"That simultaneous destruction of foxes in March be made compulsory"; "that the Government be asked to consider the opening of the Minnipa Experimental Farm for the benefit of settlers on Eyre's Peninsula"; "that this Conference strongly urges the Minister of Education to give full consideration to the curriculum of all schools in agricultural districts with a view to introducing subjects that will be of practical benefit to children of men on the land. Subjects suggested for consideration are "Animal physiology, soil amendments, plant growth, and such like for children from ages of 12 to 14 years"; "that this Conference ask the district council to enforce the Noxious Weeds Act with regard to boxthorn"; "that the railways be asked to extend the reduced rate of freight on super from February to the end of March"; "that representation be made to the Government that in the opinion of this Conference the selling of the Port Lincoln freezing works by the Government to private enterprise would be inimical to the best interests of primary production export and react disastrously upon the development of Eyre's Peninsula, and requests that the Government discuss the question with a deputation during Show Week, of delegates from Eyre's Peninsula before proceeding in the matter"; "that the next

Conference be held at Cleve." A motion dealing with legislation enabling farmers to obtain a more reasonable price for wheat was referred back to Branches.

The members of Women's Branches held a special session at which papers were read by Mrs. F. Coles, Miss J. James, and Miss Beryl Cleave, and an address was given by Mr. H. B. Barlow (Chief Dairy Instructor).

CONFERENCE OF MURRAY LANDS WEST BRANCHES.

Delegates from the Borrika, Netherton, Moorlands, Coomandook, Karoonda, Nunkeri, Kapunda, Kulkawirra, Yurgo, Copeville, and Wynarka Branches, representing the Murray Lands West districts, held their Annual Conference at Karoonda on Thursday, August 3rd, under the auspices of the Wynarka Branch. Mr. A. J. Cooke (Chairman Advisory Board of Agriculture), Messrs. W. J. Spafford (Deputy Director of Agriculture), H. B. Barlow (Chief Dairy Instructor), C. F. Anderson (Government Poultry Expert), A. H. Robin, B.V.Sc. (Veterinary Officer), R. L. Griffiths, and P. H. Suter (District Officers), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary Agricultural Bureau) attended as representatives of the Department of Agriculture). Mr. A. Hood, of the Wynarka Branch, presided, and the opening address was delivered by Mr. A. J. Cooke.

The following papers were read and discussed:—"Handling Cows on a Mallee Farm," G. R. Tregilgas (Yurgo); "Concrete on the Farm," W. R. Trestrail (Coomandook); "Care of Cream from Cow to Factory," R. Elliott (Kulkawirra); "Poultry," E. Pape (Wynarka); "The Wheat Crops in the Murray Lands West Districts in the 1932-33 Season," E. Cowled (Borrika).

It was decided that the 1934 Conference should be held at Karoonda, with arrangements in the hands of the Nunkeri Branch.

Departmental officers took part in the discussions on the papers, and, in addition, replied to questions relating to ensilage, suitable rams for Merino ewes, and the susceptibility of Merino sheep to blowfly attack.

The evening session was occupied with an address by Mr. A. H. Robin.

CONFERENCE OF UPPER NORTHERN BRANCHES.

Delegates from Wilmington, Wepowie, Willowie, Blackrock, Murraytown, Wirrabara, Jamestown, Booleroo Centre, and Morchard Branches, representing the Upper North districts of the State, held their Annual Conference at Morchard on July 19th.

Mr. F. Coleman attended on behalf of the Advisory Board of Agriculture, and the Department of Agriculture was represented by Messrs. W. J. Spafford (Deputy Director of Agriculture), H. B. Barlow, (Chief Dairy Instructor), C. F. Anderson (Poultry Expert), E. L. Orchard and J. O. Hatter (District Instructors), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary Agricultural Bureau). Mr. S. Lange (Morchard) occupied the chair and the opening address was delivered by Mr. Coleman.

Papers as follows were read and discussed:—"Efficiency on the Farm," A. McCallum (Morchard); "The Farm Orchard," P. J. Curnow (Wirrabara); "Gas Producer Tractors," L. W. Judell (Jamestown).

Questions dealing with the "Bulk Handling of Wheat," "Quality of Cornsacks," and subjects relating to livestock ailments were answered by departmental officers, and the following resolutions were carried:—"That the 1934 Conference be held at Wilmington;" "That the Advisory Board be asked to again bring under the notice of the Customs Department the inferior quality and variation in the size of cornsacks;" "That the rule making it compulsory for members to take the *Journal* be rescinded;" "That this Conference recommends that a qualified veterinary surgeon be attached to the Department of Agriculture;" "That the present Federal Commission have their powers increased to inquire into the excessive price of power kerosene."

The Evening Session was devoted to an illustrated lecture on "The Poultry Industry," by Mr. C. F. Anderson.

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board was held on Wednesday, July 26th, 1933, there being present Messrs. H. N. Wicks (Chairman), A. J. Cooke (Vice-Chairman), A. M. Dawkins, A. L. McEwin, F. Coleman, P. J. Baily, J. B. Murdoch, Dr. A. E. V. Richardson (Director Waite Agricultural Research Institute), Professor A. J. Perkins (Director of Agriculture), and Mr. H. C. Pritchard (Secretary).

Apologies were received from Messrs. Geo. Jeffrey and S. Shepherd.

Election of Officers.—Mr. A. J. Cooke was elected Chairman and Mr. R. H. Martin Vice-Chairman for the ensuing 12 months.

Life Membership.—The following names were added to the roll of Life Members of the Agricultural Bureau:—Messrs. H. Duhring (Wilmington), R. Fowler (Blackwood), P. J. Curtin (Beetaloo Valley), S. B. Manning (Euvelia), A. A. Magarey and G. W. Summers (Blackwood).

New Members.—The following names were added to the rolls of existing Branches:—Sutherland—V. Weis, G. W. Thiele; Belvidere—H. Easton, G. Cross, H. Jackson, G. Vivian; Kalangadoo—V. H. J. Moritz, G. L. Dean, J. A. McKenzie; Tantanoora Women's—Mrs. R. Randall, Miss Jessie Telfer; Cungen—A. E. Forbes, F. Malvino, P. C. Roberts, J. S. Anderson; Gawler River—K. Hillier, A. J. Carter; Mundalla Women's—Mrs. R. A. Dinning; Wilmington—S. C. Genders, G. W. Connor, Rev. S. T. Harper; Aldinga—S. A. Hall, C. S. Hall, W. Cox; Cherry Gardens—A. C. D. Blakely; Roseworthy—G. Tremlett, H. Humphreys, F. Geue, B. Window, W. Ferguson, A. Stewart; Collic—S. P. Scott, M. J. Anderson, E. P. Anderson, K. C. Scott, J. R. Lynch, H. H. Gray; Roberts and Verran—B. W. K. Hayward, A. Ramsey; Moorlands—L. A. Miatke, B. Cameron; Ramco—H. Rogers; Gumeracha—R. Laing; Kyancutta—E. S. May; Overland Corner—J. L. Jones, J. H. Schultz, C. W. Schultz; Murraytown—A. Scholz; Maltee—V. B. Schwarz, P. E. Schwarz; Chilpuddie Rock—H. Cox; Redhill—P. Kellock; Black Springs—N. Heinrich, J. Rusiack, R. Heinrich, P. Mullins, V. Gilbert, O. Kermod, E. Seigert, W. P. Heinrich; Nantawarra—C. H. Belling, L. G. Belling, E. G. Herbert, T. M. G. Dixon, R. T. Forrest, C. W. Young; Berri—W. B. James; Butler—P. R. Lange, J. Edwards, C. R. Young, A. A. Young, H. G. Turner; Penwortham—V. J. Duke, J. Stevenson; Penola Women's—Misses E. J. Shanks, M. W. Shanks, M. Aitken, L. Sandiford, R. Hill, Mrs. F. Fowler, Miss A. Fowler, Mesdames D. McAdam, E. Balnaves, W. McLean, — Winter; Kelly—L. J. Toole, K. K. A. Moore.

Number of new members for approval, 87.

Present number of members, 8,066.

Present number of Branches, 331.

The meeting went into committee to consider other items submitted to the Board.

DAIRY AND FARM PRODUCE MARKETS.

MESSRS. A. W. SANDFORD & CO., LIMITED, reported on August 1st, 1933.

BUTTER.—Usually at this time of the year production increases very rapidly, but owing to the backwardness of the season because of the dry June and July, the quantities are considerably less this year than last. A good heavy general rain is required to bring along the feed and increase the flow of milk on the farms. Quantities submitted for export so far this season are less than half for the corresponding period last year, and this indicates how vitally the dryness of the season has affected the production. It is pleasing, however, to record that the reports from London indicate better markets there, although the improvement so far has not been very marked, but with the upward tendency, the position is brighter than for some time past. Choicest creamery fresh butter in bulk, 1s. 1½d.; prints and delivery extra. (These prices are subject to the stabilisation levies.) Store and collectors, 7d. to 7½d. per pound at store door, less usual selling charges.

EGGS.—This commodity also is backward, and although fair quantities are now being packed for London, the consignments from country districts are less than was expected, but no doubt will improve with milder weather conditions. Ordinary country eggs, hen or duck, 6d. per dozen; selected, export quality eggs, 1½ozs. and over, to 10d.

CHEESE.—The South-Eastern factories are now increasing their output, and within the next few weeks exporting to Britain will be in full swing. However, in the South-East also the conditions are drier than was hoped, but indications seem to show that an improvement will take place, and already some of the manufacturers there report increasing supplies of milk. New makes, medium and large, 7½d. to 8d.; loaf, 7½d. to 8½d.; semi-matured and matured, 9½d. to 10½d. per lb.

BACON.—A strong winter demand for bacon was experienced throughout the month, and with higher prices ruling for the live hogs, values for all cuts of bacon advanced. Supplies have been sufficient for local requirements, and values are steady. Best local sides, 8½d. to 9d.; best factory-cured middles, 9½d. to 10d.; large, 9d.; rolls, 7½d.; hams, 10½d. to 11d. per lb.; cooked, 1s. to 1s. 1d. Lard, prints, 4s. 6d. per dozen.

ALMONDS.—Fair supplies of almonds came to hand from country districts, and these were readily cleared to local buyers attending the markets from day to day. Prices have continued steady both for shell lines and kernels, and at date were as follows:—Softshells and Brandis, 8½d. to 9½d.; hardshells, 5d. to 5½d. per lb.; kernels, 1s. 11d. to 1s. 11½d. per lb.

HONEY.—A better demand for honey was experienced during the last few weeks, but more especially for prime quality lines both liquid and candied. Dark-colored and inferior flavored lots, however, continue difficult to quit. Prime clear extracted in liquid condition, 3d. to 3½d. per lb.; lower grades, 1½d. to 2½d. per lb.

BEEWAX.—Selling steadily at quotations. 1s. 0½d. to 1s. 1d. per lb., according to sample.

LARD.—Is meeting with stronger demand due to the usual winter consumption, and supplies are short.

LIVE POULTRY.—The catalogues of live poultry submitted throughout July were extensive, but demand was well maintained throughout. Poulterers during the winter months carry only very light stocks, and therefore rely on the markets from week to week for their requirements. This has resulted in a steady and continuous demand, and rates for well conditioned stock were satisfactory. Prime roosters, 3s. to 4s.; nice conditioned cockerels, 2s. 4d. to 2s. 9d.; fair conditioned cockerels, 1s. 11d. to 2s. 3d.; chickens, lower; heavy-weight hens, 2s. 2d. to 3s.; medium hens, 1s. 10d. to 2s. 1d.; light hens, 1s. 6d. to 1s. 9d.; couple of pens of weedy sorts, lower; geese, 2s. 6d. to 3s. 6d.; goslings, lower; prime young Muscovy drakes, 3s. 3d. to 4s. 3d.; young Muscovy ducks, 2s. to 2s. 9d.; ordinary ducks, 1s. 6d. to 2s. 3d.; ducklings, lower; turkeys, good to prime condition, 7d. to 8½d. per lb. live weight; extra prime, to 9d. per lb.; turkeys, fair condition, 5½d. to 6½d. per lb. live weight; turkeys, fattening sorts, lower; pigeons, 4½d. each.

POTATOES.—Local new, 6s. 3d. per cwt.

ONIONS.—New season's, 5s. 6d. per cwt.

PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR SPRING, 1933.

EGGS FOR HATCHING AND DAY OLD CHICKENS**WHITE LEGHORNS.****EGGS.**—7s. 6d. per Setting of 15 Eggs. Incubator Lots, £2 per 100.**DAY OLD CHICKENS.**—15s. per dozen; £4 per 100.**BLACK MINORCAS.****EGGS.**—7s. 6d. per Setting of 15 Eggs. Incubator Lots, £2 per 100.**DAY OLD CHICKENS.**—15s. per dozen; £4 per 100.Free on Rail,
Salisbury.**DELIVERY.**—CHICKS—August and September.
EGGS—July to September.

Intending breeders should recognise the importance of establishing their flocks with only the very best of stock also, pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2ozs., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[Branch Secretaries are reminded that the following are exempt from payment of the Annual Bureau subscription:—Life members, Branch Secretaries, members appointed before August 1st, 1930, and new members who reside in the same house as (a) a life member, (b) Secretary, or (c) another member who already subscribes.

The subscription for all other members is 2s. 6d., commencing from August 1st in each year, provided that—subject to the above exemptions—nominations forwarded during the months of January to June must be accompanied by a payment of 1s. 6d. each nomination for that period.]

MEN'S BRANCHES.

SOUTH-EASTERN.

COONAWARRA.

May 11th.—Attendance, 31.

DEBATE.—For purposes of the debate, Mr. J. Kain, leader of the affirmative side, moved: "That a settler coming to the Coonawarra district be better advised to become a stockraiser than a fruitgrower." He was supported by Messrs. N. McBain and D. McGillivray. Mr. H. Richardson led the negative side, with Messrs. E. Alder and R. Childs as supporters. Strong cases were made for and against both occupations, some of the points touched on being finance required, future returns, national and economic values of each industry, known and possible diseases, possible scientific discoveries and improvements, home and foreign markets, Eastern trade expansion, prices of world parity, financial outlook and accommodation, cost of living, storage facilities and costs, transportation costs, social status, upkeep, bad debts, stability of markets and purchasers, &c. Figures were quoted by each team, and at the conclusion the adjudicators (Messrs. Reschke, C. Skinner, and C. Provis) declared the result a draw. Mr. Richardson, in moving a vote of thanks to the adjudicators, referred to the interest the Bureau had created in the community by holding its first debate, apparent by the numbers present, particularly of the younger men.

A previous meeting attended by 11 members was held on March 3rd. Mr. H. H. Orchard (District Instructor) attended, and the following points are taken from his address:—*Manuring of Fruit Trees.*—Further experiments should be carried out in the South-East. As regards experiments conducted elsewhere, allowances should be made to some extent. Use of fertilisers should receive more attention from South-East orchardists. Cultivation of soil and consequent growth of vegetation depletes soil of organic matter. This should be replaced. Potash was the most important plant food needed here by fruit trees. Nitrogen might be supplied by artificial fertilisers and stable and green manure. Supplies of stable manure was limited nowadays, but use should be made of all available. Complete manures as made up by various companies were preferable to dressings of the constituent fertilisers, being more economical. The best results on apple trees at Kybyholite came from trees treated with 3lbs. of super and 10lbs. of lime. Mr. Orchard referred to negative results obtained at Blackwood and Light's Pass from apricot trees treated with super and positive results obtained with sulphate of ammonia. Green manures supplied a local deficiency of humus. Leguminous crops were best for this; probably best of all was field peas. Another favored crop was *Purple Oat Grass*. The green manure crops should not be growing when trees were in active growth, but ploughing under must be done before that time. Advantage should be taken of the first early rains to get them sown. Alternate rows could be planted, leaving clear ground for gathering fruit, depositing prunings, &c. Top-dressed natural grasses and clovers ploughed under could to a certain extent take the place of green manure crops. As regards artificial fertilisers for this district, Mr. Orchard recommended a complete manure containing 5 per cent. nitrogen, 4.5 per cent. potash in water soluble form, and 28 per cent. phosphate at the rate of 6lbs. per tree, applied in spring.

A special meeting of about 30 members and visitors was held at Mr. E. L. Gaffney's yards on April 1st. Mr. McMillan, veterinary surgeon, of Mount Gambier, gave a practical demonstration and lecture on veterinary work on dairy cattle. (Secretary, J. Kain.)

MOUNT GAMBIER (Average annual rainfall, 30.52in.).

June 9th.—Attendance, 10.

SHEEP BREEDING.—Mr. K. Macrow read the following paper:—“The first sheep to be brought to this country were the native Cape fat tail sheep from South Africa, consisting mostly of tail with negligible wool. But the introduction of the Spanish Merino, which developed so wonderfully in its new environment, proved to be the foundation for Australia's pre-eminence in wool production, a pre-eminence that Australians not directly concerned are rather prone to undervalue and lose sight of. Captain Waterhouse has the distinction of having brought the first Merinos to Australia—29 of them. He landed in New South Wales in 1789 and was immediately offered £15 15s. per head for them, and subsequently the Merino figured in the success of all the early pioneers and squatters in their search for and settlement of good pastures. One phase of the improvement from that time in the wool-carrying capacity of the Merino is of more than passing interest, namely, the intense development of body wrinkles that went on from 1890 until about 1907, finally evolving a type of sheep after the style of a concertina. This was done on the principle that the more skin the greater the weight of wool produced, which was borne out by results. As an instance, a plain-bodied ram sold in 1874 for 680 guineas cut 12lbs., whereas one of his progeny, a mass of folds, sold in 1907 for 1,000 guineas, and cut 36lbs. of wool. However, this period (1907) saw the end of this type, as the failing constitution, lack of wool quality in the folds, and many other disadvantages, resulted in the modification of wrinkles, which are still retained within certain limits into the Merino of to-day. The conditions of climate and pasture and the type of country on which they have been bred for centuries, has stamped them with certain characteristics of wool and carcass in wide variation to each other. However, they can be separated under three groups—long wools, short wools, and mountain breeds. Of the long wools, the history of the Leicester is of most interest in that Robert Bakewell—whose name must remain honored among sheep breeders for all time—was the first man to set about improving the sheep of his country, and it was with the Leicester that he set to work in the year 1755. Bakewell's fundamental reasoning was that ‘like begets like,’ and he came to realise that certain desirable properties of parents mated together could be transmitted to their offspring until a fixed type was effected, and the rapid improvement he attained in early maturity, ability to fatten, symmetry of form, and utility of carcass was nothing short of marvellous, and almost every breed of sheep owes its improvement in part to Bakewell's Leicesters. Not only this, but Bakewell's methods proved the foundation of selective breeding of all livestock the world over, and interesting it is to realise that prior to this breeding was left entirely to Nature, resulting in the survival of the fittest and development of means to withstand the particular conditions under which stock had to exist. Other long wools used in Australia are Lincolns, Border Leicesters, and Romney Marsh. The short-woolled breeds, to which all the Down breed belong, are distinct from the long wools in their smaller, better mutton quality carcasses and finer wool. In this class the Southdown was the foundation breed, the others being developed by crossing. It is not within the scope of this paper to deal at length with each of these breeds, much as there is of interest in them all. Those belonging to the group seen in Australia, being used mainly for export lamb, comprise Suffolk, Southdown, Dorset Horn, Ryeland, Shropshire, and a few Hampshire. To the third group—mountain breeds—such sheep as the Cheviots, black-faced, and many others having no significance to sheep breeders in Australia, being breeds that are wrapped up in the conditions of the Old Country. In an effort to retain the valuable fleece of the Merino and yet develop a sheep with better mutton capacity and generally more suited to rich pastures, two breeds, the Corriedale and the Polwarth, have been established in Australia. The Polwarth was originated by the late Mr. R. V. Dennis, his objective being a fixed type of comeback sheep suited to cold country and producing a 58 to 60 quality wool. Mr. Dennis made use of the pure Lincoln, the line of breeding adopted being the mating of pure Merino and Lincoln, the ewe progeny of which cross were put back to Merino and the progeny of this cross were mated together for five generations, when they became eligible for inclusion in the stud book. The Corriedale, while originating in New Zealand, has long been established in Australia. It is a half-bred long wool Merino sheep. Mr. Jas. Little experimented, while managing a property known as Corriedale, in New Zealand, with crossing Lincoln and Merino sheep in 1866, and later many half-bred flocks were started, Border Leicesters, Romneys, and Lincolns all being

used, though the Lincoln-Merino strain was eventually most favored, a society even being formed with a stipulation that only flocks of pure Lincoln Merino blood should be registered. In spite of its mixed origin, the Corriedale is now recognised as a definite breed, with very desirable characteristics for grazing on the more settled areas, though the desired characteristics are taking longer to fix, as the crossing of two opposites, the reversions or throw-backs being more common than where there is domination either side. In the establishment of any fixed breed or type of livestock by crossing there are certain laws of breeding, without some knowledge of which success must be limited. Take, for example, a Tamworth-Berkshire cross of pigs; the first litter bears the characteristics and markings of the parents in a blended form. But in mating these crossbreds together, anything seems to happen—some marked like Berkshires, some like Tamworths, and some cross. However, by the aid of experiments, strangely enough made in the breeding of tulips centuries ago by an Austrian monk named Mendel, these variations can be controlled, anticipated, and more or less understood, this Mendel's law showing that similar results are obtained in cross-breeding both in plant life and livestock. It is only in comparatively recent times that Mendel's work has been understood and applied. Cross-breeding results either in a blending of such as red to white and producing roan, as in Shorthorn cattle, or in one breed being dominant to the other, as we find in Yorkshire-Berkshire. The latter cross results in all white pigs, but when these whites are bred they break into 75 per cent. white and 25 per cent. black. The white of this cross when mated again break into certain definite proportions of black and white, some of the white remaining pure and showing no more black when bred. But the 25 per cent. black of the second cross are recessives; that is, bred pure black with no trace of white ever appearing, though they come of all white parents. What can be understood from this in a general way is that where blending does not occur, one breed is dominant to the other, showing its dominance in color, and in further breeding resulting in a proportion of pure of either side, though the dominant breed or characteristic gains the majority. While I may not have made this aspect of breeding clear, and it is hardly possible in so few words, it nevertheless may serve to show the difficulty of fixing a breed where cross-breeding results in blending, but where there is dominance on either side the dominant characteristics can easily be retained and fixed if the dominant animal can be recognised. Inbreeding is another intriguing subject which there is no time to do justice to, but while it is a practice that is generally condemned, it has been used to obtain some magnificent animals. Experiments in consistent close breeding of pigs resulted in declining numbers in litters until finally only one pig was dropped, which failed to breed, thus ending the experiment, though when mated to outside blood it bred quite normally. Telegony is another subject allied to breeding that has interesting features. It is the name given to the question whether a dam's future breeding is impaired by being put to a sire of another breed. For example, say Merino ewes having been bred to Merinos the previous year are mated to Suffolk rams and then put back to the Merinos the following, their lambs show Suffolk markings. There are conflicting opinions on the question, a few noted breeders of horses and dogs claiming that it is so. However, scientific investigation has never discovered any evidence in support of the theory, the claims referred to probably being examples of reversion to type. In conclusion, I should like to give you as my opinion that with regard to fat lamb breeding in this district, if it were possible by some means to confine breeders to the use of one particular breed of ram, one approved of by buyers

or those with a definite knowledge of overseas market requirements, it would result in large consignments of an even type being shipped from the district, thus obtaining a reputation which would be the means of higher prices for all."

NOTE.—In the report of this Branch for the month of May there was an error. The annual social was stated as being held by the Crop Competition and the Bureau. To this should have been added the Agricultural and Horticultural Society, who were associated on this occasion.

TANTANOOLA.

May 13th.—Attendance, 14.

At the previous meeting Mr. G. Altschwager distributed poisoned grain to members for killing sparrows. Several members reported very satisfactory results.

The meeting took the form of a Question Box. Mr. G. Altschwager asked: "What is the best way to make a ewe take to a lamb if it had left it?" The general opinion was to make a small yard with hurdles and place them both in it. Mr. J. Chant found that a little oil of aniseed sprinkled on the lamb would sometimes induce the ewe to mother her lamb. Mr. J. Chant asked if it would be harmful to sow rye grass with oats. He was advised not to sow them together. The rye grass seed should be sown on top of the ground, because it should be sown very shallow. Mr. L. Osborne asked if it was necessary to always pickle wheat and barley. The general opinion was that it was safest to always pickle. (Secretary, H. Kennedy.)

UPPER-NORTH DISTRICT.

(PETERBOROUGH AND NORTHWARD.)

WARCOWIE (Average annual rainfall, 11.42in.).

June 6th, 1933.—Attendance, 19.

Meeting was held at Mr. A. F. Crossman's residence. Mr. R. Bairstow read the following paper on CEMENT FLOORS.—*Putting Down a Cement Floor.*—First of all the space for the floor should be levelled off, any holes filled up, and rammed down. Then wet the ground and leave it stand for a few hours, preferably to stand overnight. This prevents the floor from caving in and cracking. *The Concrete Mixture.*—If the gravel is clean a good mixture is 8 to 1; if inclined to be dirty, 6 to 1 would be best. Mix the gravel and cement over about three times dry, and about the same wet. This body should be put down at once. Most cement floors are put down in blocks about 4ft. square. This is done in case a crack starts. If it does it will stop instead of going right across the floor. A fair thickness is about 2in. to 3in. For a top dressing 3 of sand to 1 of cement is a good mixture. This should be put on about $\frac{1}{2}$ in. thick and worked over first with a wooden and then an iron floating trowel. A groover is used in between the blocks. The more the cement is worked the better the surface will appear." (Secretary, A. Crossman.)

WEPOWIE (Average annual rainfall, 12.46in.).

May 30th.—Attendance, 13.

SHEEPSKINS.—Paper read by Mr. D. Crocker:—"A serious loss is sustained by many farmers and graziers through lack of necessary attention to sheepskins. Instead of being carefully treated, dried, and marketed in the best condition and in the most profitable market, they are left to dry on fences or rails where they are liable to damage by dogs or cats and loss in weight and condition by the sun and weather. When stacked at a later date in a shed, treatment is not always given to prevent weevil attack. When it comes to marketing they are very often disposed of to the first dealer who comes along to the property who usually allows a liberal margin

for consigning and trade profit. The skin should be removed carefully to avoid cutting or flesh being left on the pelt, then placed in a shed after killing is finished, spread out wool side down and shortly after painted with an arsenic wash to prevent damage by weevil. When reasonably dry the skins are stacked wool side up putting one skin on top of the other. The drying process if carried out in the shade, together with the stacking of skins, results in a greater weight being retained in the skin, also better condition and quality. The arsenic wash is very cheap and made as follows:—Boil one dessertspoonful each of arsenic and washing soda in one pint of water, then add water sufficient to fill an ordinary seven pound treacle tin. The arsenic wash can easily be applied to the skin with a brush.” (Secretary, E. Roocke.)

CARE OF FARM FLOCK.—Mr. J. Fradd read the following paper:—“For this district I favor the Merino; it is a district that will grow a medium wool of good quality, and in addition the Merino is more easily controlled than are the English or mutton breeds. If a flock is kept for breeding, endeavor to procure the best class of sheep

that finances will allow. Large framed, plain bodied ewes of good constitution should be kept, using rams of similar type, with soft clean faces and wide open horns. The man who puts like to like to get like will usually come out on top, whether he wishes to breed fine, medium, or strong wool. Shearing is a good time to class the flock, marking off any sheep that do not conform to the desired type. Quality of wool, conformation, constitution, hairy breach, faulty mouth, &c., should be kept in mind when classing. It is desirable to dispose of any sheep not required, especially young sheep, before grass-seeds get troublesome. Peas can be sown if necessary for fattening the lambs. If possible, have the ewes lamb when a supply of green feed can be expected. The ewe's milk is poor in quantity and quality on dry feed and liable to cause impaction amongst lambs. On the farm where paddocks are small, 2 to 2½ per cent. of rams should be ample. Under normal conditions a ewe comes in season every three weeks; a joining of six weeks means that each ewe is on at least twice, so that a few days over the six weeks is ideal. Ewes should be crutched out three or four weeks prior to lambing; at the same time shear wool from around the udder to give the lamb a better chance to find the teat. Crutching and jetting help to minimise fly trouble, but any sheep that are struck should be attended to at once. Give ewes well watered and well sheltered paddocks in which to lamb. All water supplies must be kept very clean; sheep will not drink unless very thirsty if water is at all fouled or dirty. Maiden ewes, when possible, should be lambed down with the older ewes; the old ewes have a steadying effect on the young ones, who are usually timid and easily frightened when lambing, and will sometimes bolt and leave their lambs. Ewes should be gone through as often as possible when lambing, and any having trouble assisted. It is a good practice to sow an area with green feed for the ewes and lambs each year, thus ensuring earlier feed and a good start for the lambs, which is most essential. Tailing can be done when lambs are from four to six weeks old, providing the weather is not frosty. Before lambing commences, baits should be laid for foxes and continued throughout the period of lambing. This can be done by dragging a trail and laying baits treated with strychnine; also any lambs that die can be poisoned. Eagle, hawks and crows are sometimes troublesome and should be destroyed when possible." (Secretary, B. Giddings.)

YANDIAH.

June 9th.—Attendance, 14.

THE FARM CLIP.—Paper contributed by Mr. A. Borgas:—"Sheep are a popular sideline on the farm, and the clip is recognised as a handy asset during the year, but farmers do not pay enough attention to the handling and classing of it. Few farmers shear their own sheep, and it is essential that the services of good shearers be obtained who can handle sheep carefully and shear quickly and cleanly. Much depends on the throwing of the fleece on the table. When this is correctly done a fleece can be quickly skirted, and any soiled pieces removed. The back of the fleece is usually dry in appearance and breaks very easily, and when not removed reduces the value of the whole of the fleece to the price of that of the poorer quality. The fleece with the back removed should then be folded and rolled from the tail to shoulder, thus showing the brightest and best quality of the fleece. All bales should be neatly marked and numbered with stencil plates; fleeces, bellies, and lambs' wool being placed in separate lots. It is advisable with small lots to ask the brokers to reclass, for which they make a small charge. The farm clip is then classed by experts, interlotted with wool of its own class and then brings the highest possible price. Farmers should take great care with the clip and they will find that it will help to raise the price of wool." (Secretary, F. Jettner.)

NANTAWARRA (Average annual rainfall, 15in.).

May 6th.—Attendance, 9.

THE AGE OF THE HORSE.—Mr. W. Starkey read the following paper:—“The foal at birth has no teeth, but they can be plainly seen and soon come through the gums, two in the top and two in the lower jaw. This refers to the incisors, or front teeth, as they are easily seen; the pre-molars can be felt under the gums. At six months four incisors will be found in the top and four in the bottom jaws, the corner incisors in the top jaw will have made their appearance, and when the jaws are closed the centre incisors are in full contact, while those next to them are not quite down and the corner ones are just showing in the upper jaw. At six months milk molars are fully ‘down’ or developed, these are 12 in number, three each side of the top jaw and three each side of the lower. At one year the incisors number six in the top and six in the bottom jaw, the corner incisors do not quite come into contact, and the ‘marks’ are present in all teeth. At this age the first molar appears through the gum, the first pre-molars are also showing (wolf’s teeth), sometimes the molar will come a little sooner, but these marks will ensure the age within a month or two. At two years—when viewing the mouth from the front—the corner incisors can be seen, they are much flatter and the marks have not quite disappeared in all the incisors of the lower jaw, though they are distinct in the upper. At two years the second molars come through, making 16 teeth (incisor and molars) top and bottom. At three years there are two permanent incisors in the top and bottom, and it is advisable to have a look at a young horse’s mouth

occasionally to see if the milk teeth are not interfering with the permanent teeth. From this age until the horse has all his teeth it is a good plan to give them a look over now and then. At four years the centre incisors are level, the next two are down and are level with them, or nearly so, the corner milk teeth are well worn and the upper ones are ready to be pushed out, and the tushes show through about this time. At this age the molars are somewhat uneven, because the first pre-molar is present, the fourth permanent pre-molar has come, and the third molar is just appearing. Watch the manger about this time for crowns, and if the horse should fall back, have a look into his mouth to see if one of the crowns has joined between the back teeth, so that he cannot close his mouth properly. At five years the horse has the best mouth, he has all his teeth and they are level, though the corner incisors have not come into use on their inner edge. If the teeth are viewed from the side at this age, it will be noticed that the neck of the corner incisor is about the same as the table of the tooth; also notice the marks are going from the centre low incisors. At six years the centre incisors are becoming long when viewed from the front, the marks have gone in the centre incisor and are getting small in the next pair, and the corner incisors in the top jaw—when viewed from the side—become almost square, being a little narrower at the gum than they are on the table, and the side nearest to the tushes about the same length as the width at the gum. The marks are quite plain in the lower corner incisors though they are level—the centre with the outside. In some cases it will be found that the incisors next the centre have lost the marks, when this is the case check up the upper jaw. The inner edge of the corner incisors is worn level with the outer edge, and the central enamel of these teeth forms a ring, and the face or table of the centre incisors tends to the oval form. At this age the centre incisors are slightly whiter than at five years. At seven years the neck of the upper corner incisor shows a marked decrease in width, and the corner incisor in the lower jaw is well in advance of that of the upper—except in the case of a parrot-mouthed horse. Viewed from the front, the teeth have increased in length and the necks decreased in width. When looking at the tables of the lower teeth, all marks will have disappeared except those in the corner incisors; the marks in the upper are more oval and the centre ones smaller. At eight years the horse loses the 'marks,' though one can make a very good guess by studying mouths of horses whose ages are known. At this age there will be noticed a well-marked decrease in the width of the neck of the upper incisors, and there will be a swab spot on the bottom corner incisors. There will also be noticed a groove forming under the gum of the upper corner incisors, the grooves in the other teeth being well defined. At nine years the upper corner incisors have a well-defined hook formed by the bottom corner incisor, caused by the teeth growing out, the groove will show in the neck of the top corner incisor, and the grooves in the other teeth are well down and starting to leave the gums. At 10 years the groove on the upper corner incisor is well marked, and the increased length of crown will be noted as well as a decrease in the width of the neck of the corner incisors of the upper jaw. When viewed from the front, the top corner incisors are well in evidence, and the lower centre incisors are becoming narrower. These ages are only approximate, because after eight years the marks disappear. As the horse grows older, the age can be judged by the length and narrowness of the incisors. At 11, 12, 13, 14 the angle becomes more acute in the incisors until 20-21 years, when the incisors become very long, and in some cases they may be seen under the lips. As the good old servant's age goes on the other incisors start to part company." (Secretary, W. Hamdorf.)

SHEEP ON THE FARM.—Paper contributed by Mr. J. Harkness:—"Most farmers in this district keep a flock of sheep as a side line, and although, with present prices for the products of a flock, fortunes cannot be made, it is the little profits that come from these side lines that help to keep the farmers on the land. With sheep constantly grazing on the paddocks, the land is enriched by their droppings. Thus we are turning the grass, which would otherwise be burnt, into plant food which has a beneficial effect on the subsequent wheat crop. The flock is a source from which the farmer gets his meat supply; at the end of the year, when the balance-sheet of sheep dealings is compiled, one should not forget to credit the flock with the meat bill it has saved. Sheep in this locality are kept mainly for the dual purpose of producing wool and lambs. Being close to the market, lambs can be dispatched with very little loss of condition, and with an ideal climate the district is admirably suited for this side line. Take a ewe that rears a lamb—the lamb returns considerably more than the fleece, and this fact induces a preference for a flock with lamb-raising qualities. It is not always possible to raise a lamb from every ewe, so that one would be inclined to give preference to a ewe that, should she lose her lamb, will shear a fleece that will compensate for her keep. The crossbred ewe undoubtedly makes the best and most prolific mother, but her wool is less valuable than that of the Merino. An argument that is often raised against crossbreds is that they have no respect for fences, but keeping

fences in repair is part of farm work. Our flocks consist of about 60 per cent. cross-breeds, and we do not have a great deal of trouble in this respect. The progeny of a crossbred ewe is stronger at birth than that of the Merino, and is better able to withstand a cold snap. They mature quicker, and therefore often help the farmer to obtain an early price, which is often the best. When this ewe is culled—if in good condition—she will provide a big carcass of first-class meat, which commands a good price in the market. The Merino ewe is essentially a wool producer, but if properly mated will produce quite a good lamb. In mating for lamb-raising, do not forget that of the two parents the influence of the sire predominates. Therefore, it is most necessary to use good rams. Although the offspring of the Merino is not the quickest maturing, an extra three weeks or so in the paddock will produce a good export lamb. The best type of ewe for this district is a crossbred that will shear a good fleece, such as the Leicester-Merino. At the same time the large framed, robust Merino is not undesirable. Shearing is carried out at between the end of winter and the falling of grass seeds. This is a convenient time for a general overhaul of the sheep, such as trimming toe nails, removing ingrowing horns, &c. The ewes are usually mated about mid-November, this brings the lambs in April when green feed can be expected. Should there be a dearth of green feed, hand feeding is resorted to, chaff and oats being usually used. All our rams are of the Dorset Horn breed, they are of the low set type, and leave nice, stocky lambs. In most breeds breeders are concentrating on producing animals low set with compact body. Rams produce lambs more or less of their own type, and the export trade demands a short-bodied, well-quartered carcass. Crutching is usually done two or three weeks before the earliest lambs arrive, and the opportunity is taken to clear away any wool that is interfering with the sheep's vision, also to trim the feet, &c. The lambs are tailed on a bright, sunny morning, or when the temperature is mild. This gives the lamb a chance to get over the shock of the operation before nightfall. Lambs are considered old enough at the age of 10 days, and if done at this age the lamb does not receive a severe setback. The knife is used for tailing, and a little disinfectant is applied to cuts. Last year the lambs were kept until they dressed about 40lbs. This did not suit the export trade, but financially it was much better than accepting the higher price per lb. of export weights. The flock yielded a bigger cheque, while with the abundance of feed available it did not cost any more for the extra weight. After getting most of the lambs off to market, the ewes are usually mouthed. Those with teeth wide apart, or worn down in centre, are culled, and branded with a cull mark in a conspicuous place. These culls should be marketed as soon as they are fit for meat. Sheep that have been struck with flies are caught and the wool on and around the infected part is clipped as short as possible and dressed with kerosene and uzona. When flies are very troublesome the sheep should be yarded occasionally and all wet wool clipped from around the tails." (Secretary, M. Freebairn.)

HORSES.—Paper read by Mr. H. Brown:—"The Clydesdale is the most suitable breed of horse for farm work. The sire should be of pedigree stock, well ribbed up, and carrying a fair amount of fine hair on the legs. It is always advisable to put the best mares to the horse. Stint the mares when they are young, because they are more capable of rearing a foal than an old mare, and they develop into better brood mares. A mare can be worked up to within a week or two of foaling, so long as care is taken not to give the mare any heavy work. Mares should be put to the horse in time to foal in August. Allow the foal to run with the mother until it is nine months old. The mare should be well looked after while suckling her foal, or her supply of milk will soon go off, and a stunted foal will result. Once the foal is weaned it is sometimes turned out in the paddock to fend for itself. This is a mistake. The foal should have every care, because later on it will have to replace one of the older horses on the farm. Young horses should be handled when they are 2½ years old. Care should be taken when handling them. On no account should they be hit or knocked about, they do not forget ill-treatment, and are likely to be more troublesome. Catch the young horse and tie him up over night, and in the morning he will usually lead. Do not keep the colt tied up too long without feed and water. Put the young horse in the wagon, here he will be properly under control, and there is not much chance of him getting tangled up in chains. A young horse should not be worked for more than two or three hours for a start. A good fitting collar should be selected for the colt, and if the shoulders are washed with hot water after he is unharnessed there will be little danger of sore shoulders." (Secretary, C. Zippell.)

USES FOR WOOL AND SHEEPSKINS IN THE FARM HOME.

[By MISS ELLIE CAMPBELL, Dip.Dom.Econ., Inspector Domestic Arts,
Education Department.]

On the farm where numbers of sheep are handled during the year there is very often a quantity of wool and pelts that are difficult to turn into cash, for freight is high, and the return is not always remunerative. Thus the question, "What can be done with them?" is often discussed. But it is surprising how many useful and comforting articles can be made from surplus wool and sheep skins, and great is the feeling of satisfaction when the finished articles are appreciated and praised. It is worth all the thought and effort put forward to use the material on hand.

There are two types of articles that can be made, one in which the wool detached from the skin is used, and the other where the skin is tanned and used with the wool on the leather.

TO PREPARE THE WOOL FOR USE.

When wool only is to be used it is removed from the skin with sheep shears or scissors, and has then to be cleansed and freed from yolk.

Wash the wool in hot soap suds—several washings may be necessary. Wash by moving and dabbling the wool in the soapy water, being careful not to tangle the staples, otherwise the wool will have to be teased, and the process is tiring. Wash thoroughly until there is no yolk or stickiness left in the wool, then rinse under running water (if possible) until the water runs clear. When dry, shake well to remove any burrs and to free the tips of the wool. The wool should be white and fluffy, and may be stored in calico bags or spare pillow cases until sufficient wool has been cleansed for the task contemplated. The foregoing method has been used successfully by some housewives, but the system adopted and recommended by Mr. Henshaw Jackson is as follows:—

"The first and essential requirements are soft water and good soap, and secondly, vessels of sufficient capacity to soak and rinse off the wool, for which three large washing tubs, preferably of oval shape, will be found suitable.

"The method is to tease or break up the wool so that it is in an open and loose condition before placing it in the washing liquor, then fill the first tub three parts full of hot water, about 140° F., and mix in with it ½ lb. of good soft soap to make the scouring liquor. Soak the wool in this for about 20 minutes, working it about in the liquor occasionally with a small garden fork; then fork it through the other two tubs, which should be three parts full of hot water, about 120° F., and contain a little soap, say, 2ozs. each. It will be better if the wool can be squeezed through a wringer or mangle between each wash.

"As the wool is liable to mat or rope if handled when wet, care should be taken when agitating the wool in the tubs that it be not lifted out of the water, and when transferring from one tub to another, lift it on the fork in one mass, a little at a time and drop it into the water without too much handling. To get the best results, each separate forkful should be 'swished' or worked through the two rinsing tubs by itself, returning to the first tub each time for a fresh forkful.

"A good scouring soap can be made by dissolving 1lb. (one pound) of caustic soda in three pints of water. Then melt 6lbs. of tallow free from salt, and when both are cool pour the soda liquid into the melted tallow, stirring it well at the same time. Let it stand overnight, and when cool (about blood heat) cut up the soap thus made and boil 10lbs. of it in 10galls. of soft water and add 1lb. of caustic soda; this will give a good soft soap."

MATRESSES FOR BEDS.

For perfect rest and relaxation whilst sleeping, it is necessary to have a firm mattress; one that will not go into a trough when being used, although it must be very comfortable and restful to lie upon; a wool mattress (Plate I., Figure 2), will fill all these requirements. It will be as cosy, yet not over-heating, as a feather mattress. With careful tabbing there will not be the great expenditure of exertion to smooth the mattress when making the bed each day, as the tabs keep the filling in place.

Plate I.

Scoured wool (Plate I., Figure 1), will wear indefinitely, and will not lump like flock, nor powder away like kapoc. This will reduce the amount of fluff to be swept from under the bed each day.

Materials Necessary to Make the Mattress.—Procure a good quality linen ticking and allow 2in. for turnings and also 2in. extra for each foot in the width of the bed to be taken up with the filling. For example, if the bed measures 6ft. by 3ft.,

the ticking will measure 6ft. 2in. by 3ft. 8in. It is necessary to have two lengths of ticking, also a strip of ticking 5in. wide by 18ft. long; this is to form a 4in. side for the mattress. A much improved appearance is gained if the sides are piped, with the same material or material of another colour, but the piping is not essential.

To Make the Mattress Casing.—Fold a 1in. wide strip of material in two and insert between the top ticking and the side strip, the fold to project $\frac{1}{2}$ in. on the right side of the ticking to form the piping, machine together, taking particular care to have the corners secure and smooth. It is a good plan to put two rows of stitching around, as there is a strain on the seams. Follow the same method with the bottom ticking, but leave half of each end open to put the filling in—it is easier to work from both ends as the mattress is so long.

To Fill the Mattress.—Thirty pounds of wool are necessary for a double bed mattress. Pack the case firmly with the scoured wool, be sure that the wool is not matted together when being used. Keep the mattress slightly higher, or thicker, in the centre than at the sides, for when it is in use the stuffing is forced to the sides, and it will always spoil the appearance of the finished article if hollow in the centre. When sufficiently packed from both ends sew up the ends, not forgetting the piping.

Now it is necessary to tab the mattress, although this tabbing takes time and is a little awkward to do, it means a lot to the life of the mattress and saves much energy when turning and smoothing the mattress each day. The tabbing simply keeps the stuffing in position. In a kapoc-filled mattress the kapoc powders away and then there is nothing to support the twine, and the leather tabs become detached; but wool does not powder away as kapoc does. Leather, felt, or wool tabs may be used, but a soft leather is to be preferred. Felt or wool tabs are likely to harbor moths; of course the moths cannot get into the stuffing for they do not like linen or cotton materials, and whilst there are no breaks in the ticking through which they may enter, the mattress will be quite free from these pests. Use a mattress twine to sew on the tabs, or a strong linen thread will do quite well. The tabs should be opposite one another on top and bottom of mattress; they should be placed so as to form triangles or diamonds with a side of 12in. to 15in. The sides do not need the tabs sewn on, but it is very advantageous to stab the side and sew the wool in place. Perhaps three rows of sewing, being alternately placed around the sides, will be plenty.

PILLOWS.

Pillows to match the mattress, as seen in Plate I., Figure 3, could be made, but they would not require to be piped nor stabbed; and they will be more comfortable if they are not packed too tightly.

QUILTS.

The size of quilt for a double bed is usually 60in. by 66in., and it takes about 5lbs. of wool for a quilt similar to the one shown in Plate I., Figure 4. The cost to buy one filled with fleece wool is in the vicinity of 50s. to 60s.

Over the foundation material, a good sateen or good quality unbleached calico is very suitable; place a piece of butter muslin which should be a good 2in. larger all round than the size of the quilt. With a dark thread for tacking, or a pencil, outline the proposed design of quilt, marking the material into the various divisions. There will be required another piece of muslin to cover the wool (muslin is suggested, as it will not add much weight to the quilt, and yet will keep the wool together and make the task much easier). Over this is placed the decorative covering of the quilt. Choose colours that will wear and that will add brightness to the room, but they must harmonise with all the furnishings. Cut the decorative covering to the size and shape required—generally an oblong 20in. by 26in. for

the centre, and four long strips 5in. in width, allowing liberal turnings on all pieces. Contrasting colors may be used; if so, they are placed on alternately. Of course, the top covering may be one piece, then it is not necessary to cut it into strips, but be sure to place the centre on the centre of muslin.

To Make the Quilt.—Having outlined the foundation muslin, tease the wool and place a liberal amount on the centre, cover with muslin and oblong piece of covering, and tack down. There is no need to turn in the edges of centre piece as the first strip with edge turned in is placed on this and machined into position, stitching as near the edge of the strip as possible. The corners of the strips should be smoothly vandyked or mitred, and all the joins should be in a straight line in order to have a pleasing effect. Press the seams before joining the covers.

To make a vandyke corner take the strip and double it keeping the edges even; the fold should be at the point (a) marking the corner on the longest side of the strip. Now fold back point (b) until a right angle triangle is formed, having the crease (c) at 45° to the edge of strip. Crease well and machine on the crease. The result should be that the strip forms two sides of a square.

If care is taken to get the point (a) correct

for each strip there should be no difficulty in getting the seams to form a continuous line. This is essential for a good effect when quilt is finished. Only the inner edge of each strip, except the final strip, need be turned in, as each successive piece is placed on top of previous piece. Be careful with the corners. If a mitre is required the folded triangle is cut away after stitching along the crease (c), but there is no advantage in so doing.

Now raise the first strip and place the wool in position between the muslins. It will be found easier to manipulate if a short section is filled and tacked down at a time, instead of trying to do the whole side. Proceed with the second and then the third strips, keeping the corner joins in line with the previous joins. Before stitching down the outer edge of quilt see that the muslin is turned in so that a firm edge is secured. This edge may be piped if desired. Piping is just

for effect. When machining the long sides avoid having to pass the whole of the filled quilt under the arm of machine. Do not have the outer strip as well filled as the centre, although it must not be loosely filled, for if it is too full it will not lie smoothly on the edge of the bed, but rather curl back on to the top.

Work one or two eyelets in centre of quilt if no design is stitched across the centre. This is to hold the wool in position and not allow it too much room to move. Also it gives a finish to the quilt.

TEA COSIES.

The object of a tea cosy is to keep in the heat around the tea pot. As wool is a poor conductor of heat it is an ideal article with which to fill the cosy. Make a casing of calico and fill it with teased scoured wool, then mount it with an attractive cover made of wool embroidery on a fine canvas foundation. A most useful and pleasing article is the result (Plate I., Figure 6).

TABLE MATS.

If wool-filled table mats (Plate I., Figure 5) are used there will be far less likelihood of the table being marked with hot plates. Also, as they will be softer than cork mats, the plates will sink into them slightly and thus the plates will not be continually slipping away or moving whilst father is trying to carve the joint. These mats may have a decorative cover slipped on them before using; the cover could be embroidered either in white or coloured threads.

IRON HOLDERS.

How annoying, not to mention how painful, it is to burn the fingers by catching hold of a hot iron or saucepan handle! "Prevention is better than cure," so the proverb says, therefore, to follow the advice make a wool-filled holder (Plate I., Figure 8). All wool-filled articles can be easily washed and dried.

INNER SOLES.

Winter time often means cold feet, and this can be partly avoided by having wool-filled inner soles (Plate I., Figures 7 and 7A). Cut two pieces of calico the size of the sole and machine together, leaving the heel open. Turn seam inside and fill with wool, then sew up the heel. They may be quilted, if desired, but the quilting will take up the material and cause the finished sole to be slightly smaller—this can be allowed for when cutting out the soles. Also, quilting makes the sole much firmer. Children love a sole into which their little feet can sink. These inner soles can be washed, and they dry fairly quickly.

SMALL MOP FOR LAMP GLASSES.

A small mop (Plate II., Figure 3) is very handy for cleaning lamp glasses or bottles or jars. A small piece of wood (the model was made on a butcher's wooden skewer), smoothed in order to avoid splinters, has the scoured wool securely fastened on to the end by binding it with strong fine string. Take care to cover the end of stick. It is so easy to keep clean and sweet. Rinse well after use each time, then dry and hang where the air can circulate around it.

TOYS.

All toys that need filling are best if filled with wool, as they are light and soft. For the little chap who is just commencing to run about and play with balls, there is nothing more attractive than a multi-colored, soft football, one that is not hard for a child to kick, yet is soft and cosy for him to hold—even father will not be able to resist having a kick. Small lengths of wool may be knitted into strips, narrow at both ends, and then sewn together and filled with scoured wool. The ball illustrated in Plate III., Figure 8, has been worked in moss stitch. A harder ball for an older child can be made by using a tennis ball and tying string around it, making eight strands, then with scraps of colored wool work the cobweb stitch over the strands of string, mixing the colors as the ball is covered.

To work the cobweb stitch pass the needle under the string and come back over and under the same string, then pass needle under the next string and continue in this way. An illustration in Plate III., Figure 9, shows an old tennis ball with the cobweb stitch started.

Dolls, teddy bears, golliwogs, and animals can all be filled with wool. They are washable and do not wear away nor lose their shape as do those filled with kapoc or sawdust. The toys are soft, warm, and cuddlesome.

A TEDDY BEAR.

Teddy, as seen in Plate III., Figure 6, is crocheted, and small round pieces of cardboard (about the size of a 2s. piece) are placed in the end of the legs and arms, where they are to be sewn to the body. This helps to keep the limbs in good shape.

A GOLLIWOG.

Golliwog (Plate III., Figure 5) is knitted in garter stitch, the eyes and mouth are buttonholed with white wool. The hair is knotted on with the stitch used in making a pile wool rug, as is explained for the mat (Plate IV., Figure 2). Red buttons and a red flannel tie or bow complete the toy.

PREPARATION OF SHEEP SKIN BEFORE USE.

For the other type of articles made from the skin there is more preparation needed, as the skin must be tanned in order to preserve it. The scouring of the wool and the tanning of the skin is proceeded with at the same time. The skin of a lamb is much better for the smaller articles, as it is not necessary to clip the wool. For mats and door slips the sheep's skin with longer wool is very effective, and it may be cut into the size desired before tanning.

DRESSING THE SKINS.

Try to keep the skin whole while treating it; although this is not essential, it is often possible to obtain more articles with careful planning from the whole skin than endeavoring to fit patterns on to small pieces. Remove as much fat and tissue as possible from the flesh side of the skin, using a blunt knife or similar article. This saves a considerable amount of energy later, for the skin must be free from all these scraps when finished. Have at hand about 9qts. of bran, 3lbs. of alum, 2lbs. of salt, 1lb. of saltpetre, 1½lbs. of good household soap, and plenty of water.

If the wool on the skin is very dirty and contains a high percentage of yolk, it will be advisable to soak it in bran water for 24 hours. Use 1qt. of bran to 4galls. of water. The bran water is very soft and has a cleansing effect. It is not necessary to strain the bran water before immersing the skin, nor is it necessary to rinse the skin before proceeding with the tanning.

TANNING THE SKINS.

Melt 1½lbs. alum, 1lb. salt, ½lb. saltpetre, and 12ozs. soap in hot water, add to this 2qts. of bran and sufficient cold water to cover the skin. Stir well to get the bran mixed. Soak the skin in this liquid for 24 hours. Work the skin several times whilst it is soaking, and press well down, although it should not be too tightly packed, for the solution must penetrate to all parts of the skin. Lift out and squeeze out as much water as possible. Dissolve the remaining 12ozs. of soap and add 2qts. of bran with sufficient cold water to cover the skin. Soak the skin, working it as much as possible for another 24 hours. Lift out and rinse well—under the running water is the easiest. It is necessary to get all the soapy and greasy water out, so the water should run clear. If the wool is still sticky with yolk, wash it again and again in very hot soap suds, and rinse well. Now dissolve 1lb. alum, 1lb. of salt, and add sufficient cold water to cover the skin. Allow

the skin to remain in this solution for another 24 hours. Remove the skins and squeeze out as much water as possible, then place the skin over a fence or box to drain. When nearly dry rub into the back a mixture of $\frac{1}{2}$ lb. of alum and $\frac{1}{2}$ lb. of saltpetre, well powdered. Then rub the skin with a piece of pumice stone, or a piece of brick, to remove any loose fibres and also to soften the leather. The leather must be made soft and pliable in this stage. The wool should look fluffy, clean, and white. It will probably need a little combing to free the tips.

Plate II.

CUTTING OUT THE ARTICLES.

With a soft pencil draw the outline of the desired article on the leather side of the skin, then with a sharp knife, or razor blade, cut the skin along the lines, and when the pieces are separated the wool will part easily. If scissors are used the wool is often and unavoidably cut in the wrong place, causing a lot of trimming of the leather as the work proceeds.

To Join Pieces of the Skin.—Place the edges of skin together and top sew with a strong thread (24 cotton). Do not take a very small stitch, as the edges of skin will tear easily. Free any wool that has been caught down with the stitches, and the join will not be easily detected.

BEDSIDE MATS.

After tanning the skin as previously explained, the centre part can be cut out for a floor mat (Plate II., Figure 1). Any skin could be used instead of sheep skin. The mats are quite serviceable without a lining, but some folk like to have them lined, and a small edge of lining is allowed to project, forming a mounting for the skin. The disadvantage of having the mats lined is that all the facings and linings have to be removed when it is desired to wash the mat to freshen it, then when the mat is dry they have to be resewn into place. They wear well unlined, and very often do not slip as much as lined mats when used on polished floors. A good depth of wool on a mat has a most attractive appearance when used on the hearth before a fire; it gives every suggestion of comfort. The mats may be dyed if desired. Of course, they cannot be boiled, as that would ruin the leather.

FLOOR POLISHERS.

How convenient it is to have a polisher on a long handle so that the necessity to crawl on the floor is abolished (Plate II., Figure 5). Have a block of wood, fairly heavy though not excessively weighty, and in the top of the block have a broom handle fixed. Cover the face and sides of the block with sheep skin, wool side out, taking special care to completely cover all corners with the piece of skin. Tack on the skin to make it firm and secure. This polisher is such a help, as with the corners covered it is possible to rub up the surrounds in all rooms without marking the skirting boards. When dirty it is very simple to wash, and it does not take long to dry. Of course, instead of the long handle a short strap may be attached to the top of the block, and the hand slipped through the strap when the polishing is to be done. These polishers may be any desired size, but if too large they are too trying to push about quietly, and for the purpose 9in. by 12in. is a good convenient size.

FURNITURE DUSTERS.

To be able to keep a supply of good soft dusters is a big problem in most households, especially when dusters are also in demand for the car. Highly polished furniture requires a very soft duster with no attachments, such as buttons or hard seams, as these scratch the furniture.

Here is the ideal— a piece of sheep skin a little larger than the hand (Plate II., Figure 4). Sew to three sides of the leather a piece of calico, leaving one end open to enable one to insert the hand. When dusting, the duster is slipped on the hand and the fingers can still bend sufficiently to allow all grooves, carvings, and turnings of the furniture to be properly dusted. The staples of wool collect the dust instead of flicking it from one place to another.

When the duster is soiled just hold it under the running water and wash with soap, then rinse well, hang it in a breezy place to dry. It quickly dries, and there is always a clean soft duster on hand.

BOOT POLISHERS.

These are made very similarly to the furniture duster, only two pieces of skin are sewn together by top sewing, leaving one side open for the fingers to be inserted. Being a light, soft duster, it can be moved very quickly, and the result is a high polish on the shoes. Again, these dusters do not wear away as quickly as do the cloths.

INNER SOLES.

During the winter time it is sometimes difficult to keep the children's feet warm and dry. Their little shoes are not heavily soled, but with inner soles cut from the sheep skin and the wool clipped down a little (Plate II., Figure 6), the most cosy shoes can be obtained, little toes can be kept much warmer, and the additional layer of leather, although very thin, will help to keep the feet dry. At first the soles seem to fill the shoes, but as soon as the pressure of the feet has

pressed the wool into place there does not seem to be any inconvenience. These inner soles, of the necessary size, will also help to give adults comfort during winter. Think how the chilblains can be saved!

Plate III.

POWDER PUFFS.

Many folk like to use face powder, and there is always a striving to have pretty dainty toilet ware. If a small circular piece of thoroughly cleansed sheep skin is lined with satin, and a dainty edging put around, the result is a useful and neat

powder puff that any lady or girl would be delighted to receive as a gift (Plate II., Figure 8). They are washable, thus a change of powder will not necessitate additional puffs.

POWDER PUFF FOR THE BACK.

The puff for the back is made by two pieces being joined together and filled with scoured wool, then tacked on to a long handle which has been inserted into the filling (Plats II., Figure 2). The handle can have ribbon plaited around it, or it can be lacquered to harmonize with the other toilet requisites.

ANIMAL TOYS.

In making models of animals draw the outline on the leather side and cut along the line with a sharp knife or razor blade, then when the leather is separated the wool will part easily. Place this side on the skin again, two skin sides together, now draw around this piece to mark the second side, and cut it out—this assures that the two pieces are not for the same side. If possible cut the tail and the legs in one piece with the side, this does away with the constant sewing on of the various pieces, as they cannot be pulled off so easily. A small strip about 1½ in.

wide at one end and sufficiently long to come from neck to tail, but shaped to a point to fit into the neck, and four small pieces to make inside of the legs; and two pieces for the ears are necessary for all animals.

The joining should be done with a strong cotton, and a fairly large stitch, about 3/16in. should be made each time—a smaller stitch often tears the edge of the skin. The accompanying diagrams are drawn to scale, and by increasing or reducing the size of the squares, models of any discreet dimensions can be made.

SQUIRRELS.

To Make a Squirrel (Plate III., Figure 2).—Cut two pieces as in diagram, place the skin sides together and join by top sewing, starting at the tail, and when it is done stuff it with the scoured wool, and any clippings of wool from the skin when cutting out the animal. It is very much easier and more interesting to complete the various small parts as they are sewn up. Top-sew along the back, taking a fair amount of the skin, about 1in. on each side, with each stitch, sew around to the chest. Then fill the head. Before joining up the remainder of the body, sew

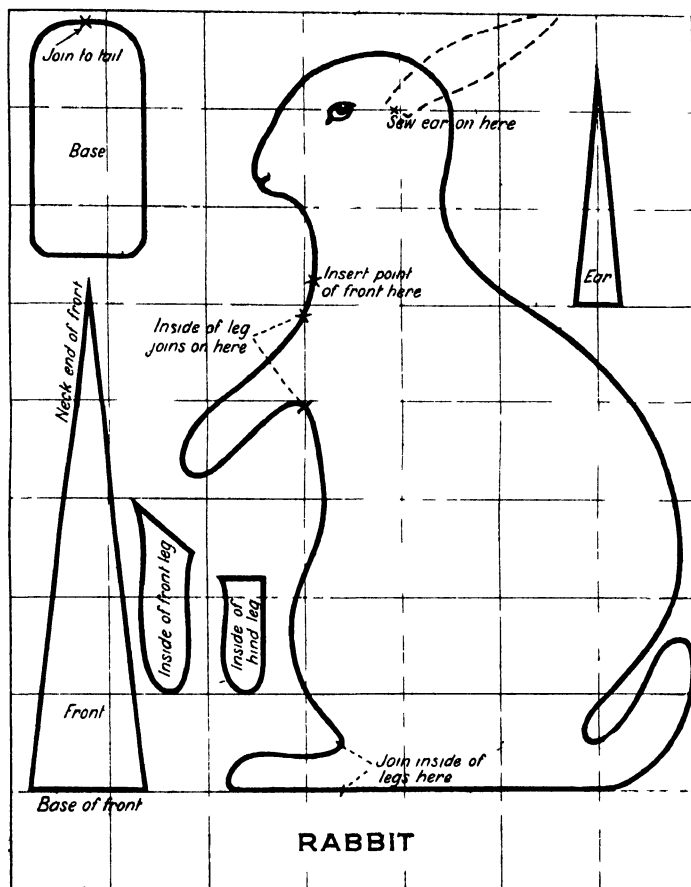

the small pieces on to each leg, making as it were, a pocket. Do not stuff the legs until they are sewn on to the front piece. Join the point of front piece to chest and continue sewing along one side, taking care to join on the inside of legs only. When sewn nearly to the tail, join the other side. Stuff the legs very firmly, otherwise they will bend after a little use, then stuff the wool into the body, using a pencil or a long, thin stick to work the stuffing well along the body. Make the chest and the sides very firm.

When as much wool as possible has been worked in, the base must be sewn into position, joining the front, the back of legs, and the tail.

For the eyes use black mending wool, about six satin stitches on top of one another worked each side of the head, and the white wool slightly clipped away around it. A piece of colored ribbon around the neck will give a little color to the toy.

RABBITS.

A rabbit (Plate III., Figure 3) is made similarly to the squirrel, but the ears are long triangular pieces of skin. To sew the ears in place, double the base of triangle and just part the wool at the side of the head and securely sew on the ear, then ruffle the wool back into place to hide the join. Do the same on other side. When the sewing is finished comb all the wool and make it look quite fresh.

DOGS.

The dog (Plate III., Figure 4) has its ears sewn on so that they will hang down. The wool from top of nose is clipped fairly short. The diagram shows the pieces necessary for the dog.

CLEANING THE TOY ANIMALS.

When these animals are washed do not immerse them in the water, for it would soak through the wool used in filling. If they are held under the running tap and rubbed with soap, it is all that is necessary. To dry them suspend them from the clothesline, first upright, but before they are properly dry they should be inverted in order to have the ears and tail keep their proper shape. They will only do so if dried the way they are required.

DIAGRAMS OF TOY ANIMALS.

Diagrams of only a few animals have been given, but the method of making each animal is very similar. These diagrams can be enlarged to any size required by enlarging the squares on the paper.

WOOLLEN GARMENTS.

The most popular wool work is the making of garments with woollen thread. Some are knitted, crocheted, netted and woven. There are hundreds of books giving directions for making all manner of woollen goods, and so only a very few will be dealt with in this article.

Should anyone possess a spinning wheel, it is far more interesting to spin the thread, dye it, and then weave it in some way into a useful article. The art of spinning is to retain a steady, even, and fairly slow spin of the wheel, and all the while to be feeding the staples, just a few at a time, into the spool attachment. It is very easy when the necessary skill has been acquired. Do not treadle quickly, and never be in a hurry to get all the wool into the spool.

WOOL MATS.

Plate IV. shows the making of a small mat (Figure 2), worked in the pile rug stitch. Figure 1 shows the canvas that has been used as a foundation for this mat, although a coarser one can be obtained. Turn in the edges of canvas and bind with wool, making firm, clear edges. The wool that is used to bind the canvas should harmonise with the wools used in the design. It is necessary to have the wool cut into equal lengths, this is best done by winding the wool around a smooth, even board, then cutting down one edge. Take a single piece of wool and double it in half, with a crochet hook (Plate IX., Figure 1) draw the loop through two holes, passing under one cross thread. Now pass the ends of thread through the loop and draw it up tightly, keeping the ends even. The tighter this is drawn up the more securely will the wool be fastened to the canvas. Put the threads closely

together if a very thick mat is desired, and the wool should be of such a thickness that it will fill each space. The foundation can be made of hessian, just as successfully as of canvas.

The mat may be lined and bound if wished, although the wool is neat and flat on the reverse side, yet it will wear longer if lined.

There are various tapestry stitches that are suitable for making hearth rugs, mats, and stool covers, but they do not give the loose pile to the mat.

A mat worked in tapestry stitches is much lighter than one worked with a pile. Stitches such as the herring-bone, cross, and diagonal satin stitch, and their variations work up very well, and if colors are worked in the result will add brightness to the room. Plate IX. illustrates several tapestry stitches:—A.—Pile Stitch, B.—Diagonal Satin Stitch, C.—Lock Stitch, D.—Chain Stitch, E.—Fern Stitch, F.—Signal Stitch, G.—Tile Stitch, H.—Herring-bone, I.—Knotted Stitch, J.—Cross Stitch, K.—Padded Half-cross Stitch, L.—Half-cross Stitch, M.—Half-cross Stitch. Figures 1 and 2 of Plate IX. illustrate crochet hook used for rug-making.

Plate IV.

WORKED TEA COSY COVER.

Figure 1 of Plate V. shows the fine canvas that has been used as the foundation for the tea cosy shown in Figure 2. The design is carried out in perpendicular satin stitch. Care must be taken to be sure that the stitches are kept regular by covering the same number of threads each time. The hem is turned up $\frac{1}{2}$ in. and a cord of wool is fastened along the join, and two woollen pom poms mount the top.

The house has been worked in yellow and red. The lawns in two shades of green, the trees in green with black trunks, and the pathways in fawn.

The reverse side may be worked similarly or worked as a gay garden, keeping the stitchery confined to the upright satin stitch.

The two sides are worked and then joined together, having about $\frac{1}{2}$ in. turnings. The work may be pressed on the wrong side, using a damp cloth under a fairly hot

iron. Whilst pressing, the opportunity should be taken to pull the work into a good shape. Often when working on canvas the work gradually gets out of shape through having an uneven tension on the thread, but when the canvas is damp and hot it can easily be pulled back again and then pressed dry.

TRIMMINGS.

Motifs are such useful things to decorate a child's crib cover, or little rompers, and tunics. They can be easily made or else bought ready made, and then sewn on to the other material. Muslin is usually the foundation, and after the design or outline has been drawn the colored wools are worked in by either the looped

Plate V.

rug stitch, previously explained, or the horizontal satin stitch, or a combination of both stitches, as in the rooster (Plate VI., Figure 4). Where necessary the outline may be brought into prominence by the use of the stem stitch.

The Rooster (Plate VI., Figure 4).—The rooster has been worked in two-ply wool. Red has been used for the comb, which was worked in short satin stitches. Yellow wool was used for the feet.

The Twins (Plate VI., Figure 5).—These toys have been worked in three-ply wool, and the hair and faces were worked with silk, the short satin stitch being used. A deeper pile was left on this motif than on the rooster.

Micky Mouse (Plate VI., Figure 6).—Micky is a favorite of the children's, and this one has been worked on black material for the ears and top of body and white material for face, hands, trousers, and shoes. Then the white pieces overlap the black pieces.

Plate VI.

Teddy Bear (Plate VI., Figure 7).—This little teddy bear has been worked in horizontal satin stitch, working in two tones of colored wool. The outline of limbs has been defined with stem stitch worked in black silk.

Woollen Brooch (Plate VI., Figure 3).—With a woollen frock a brooch made of wool is in keeping. The one shown is made on an old curtain ring, button-holed all round, with the purl of the stitch to the centre of the ring. Across the top

half of ring draw a number of threads from side to side catching them into the purl. They must be very close together. Over these threads work a series of French knots, using various colored wools. From the centre work another group

Plate VII

of green threads, at right angles, down to the purl of ring stitches. This will form the stem of the posy. Do not use a coarse wool or the effect will be spoilt.

Trimmings for Berets (Plate VI, Figures 1 and 2) — A plait of woollen threads gives a very soft effect around the edge of a beret. This trimming could be made to work in the various colours of the jumpers and scarf that is to be worn with

the heret. For a trimming that is required to be a little firmer, there is the woollen astrachan. These trimmings can be bought by the yard, and they are relatively cheap.

Woollen Ties (Plate VII., Figure 3).—It is one of the worries of a gentleman's life to keep his ties free from creases. Very often the plea comes forth for the tie to be pressed. Well here is a tie that does retain its shape and freshness much more than the silk or cotton material ties. They are woven in various colors and patterns, and may be purchased at any of the leading drapers.

KNITTED AND CROCHETED ARTICLES OF WOOL.

Nearly everybody can knit and crochet these days, there has been a revival of these particular methods of fancy work, and it is most interesting to be working out a pattern and all the while watching the garment grow. The styles of garments and the stitches that can be used for each are far too numerous to be enumerated. and they can be obtained from many books, therefore, in this article just typical garments and articles are mentioned. Whatever can be made for a small child can be enlarged and made for an adult. The successful slogan was "All's well if all's wool," therefore use as much wool as possible.

The Circular Bed Jacket (Plate VII., Figure 1).—The illustration is of a most attractive bed jacket worked in crochet, a very simple stitch is used—a long treble. The whole garment is double, having straight sleeves within the fuller outer sleeves. The jacket was made from the directions given in "Woolcraft" book.

When the jacket has been folded in half, any trimming desired may be sewn on to the fold to give a softening effect around the neck.

Morning Tea Set (Plate VII., Figure 2).—Here is illustrated small tea and egg cosies with a teapot holder completing the set. This set was prepared for a breakfast tray, so that mother could have a real rest on Sunday morning. The articles are worked in the fluted garter stitch. Two colours were used—green and white. A small china figure is fastened on top of cosy, but a loose tassel is on the egg cosy. The holder has been lined with a piece of plain knitting.

Child's Slipper (Plate VII., Figure 4).—A warm comfortable slipper is made by using wool and crocheting in any simple stitch when the upper is joined into shape, it is then sewn to a leather sole and an inner sole of sheep skin (Plate II., Figure 6) is placed inside. A cord or tie is laced around top of slipper to complete it.

BABY'S OUTFIT.

Coverlet (Plate VIII., Figure 1).—Over baby's pram a little coverlet looks so cosy and soft. This "Bunny Cover" has been worked in the simplest of stitches, the centre is in stocking stitch and it has a border of garter stitch. The three white bunnies were worked in chain stitch after the coverlet had been pressed. It may be lined to make it a little warmer.

Baby's Hug-Me-Tight (Plate VIII., Figure 2).—These hug-me-tights are so simple to make, all rows of plain knitting. Do the cuffs on finer kneedles so that they will grip the wrists. Finish the edges with a row or two of crochet, using the silky rabbit wool. Turn down a small piece around the neck and thread it with the ribbon—this double piece makes the wrap much more comfortable around the neck.

Baby's Coat (Plate VIII., Figure 3).—A knitted coat is very warm and light in weight. The coat illustrated has been worked in the "Feather and Fan" stitch, with the yoke and cuffs of "Moss" stitch.

Small Bloomers (Plate VIII., Figure 4).—These little under-garments ensure that the small child is warm—they are worked in "Ribbed Moss" stitch. They may have elastic or ribbon around the waist.

Plate VIII.

. Plate IX.

Fig. I.

Fig. II.

Knee Caps (Plate VIII., Figure 5).—For those driving cars or for dear old granny, who feels the cold in the joints, there is great comfort in a pair of knee caps knitted in wool. They must be knitted in rib and sufficiently tight to grip the leg above and below the knee. If too tight they will be very uncomfortable, and might interfere with the circulation.

Baby's Frock (Plate VIII., Figure 6).—The little dress illustrated was knitted in two-ply wool, with a lacey stitch for the skirt, but plain for the yoke and sleeves.

A set-in sleeve sits and keeps its shape better than a sleeve knitted in one with the bodice.

It is best to have children's wear dainty and attractive, but in winter it must be warm and soft. A woollen garment will supply these necessities.

Gaiters (Plate VIII., Figure 7).—These woollen gaiters have been knitted with sufficient length to protect the leg from above the knee to the toes. It should be shaped to the leg in order to keep it up.

Mittens (Plate VIII., Figure 8), *Booties* (Plate VIII., Figure 9), *Slippers* (Plate VIII., Figure 11), and *Shoes* (Plate VIII., Figure 12), have all been knitted to complete the outfit in the simple stitches.

Bonnets (Plate VIII., Figure 10).—The bonnet shown was knitted to go with the jacket in "Feather and Fan" stitch. An extremely warm bonnet will be procured by lining the knitted bonnet before it is worn.

SUMMARY.

1. A great number of useful and comforting articles can be made from surplus wool and sheep skins.

2. Wool must be freed from all grease, dirt, and foreign matters.

3. Hot soap suds will clean the wool.

4. When cleaning the wool should not be tangled or matted together.

5. To store wool so that it is protected from moths it should be kept in fine calico bags.

6. Scoured wool is useful for stuffing mattresses, pillows, quilts, tea cosies, table mats, iron holders, inner-soles, and toys of various kinds.

7. To utilise sheep skins to best advantage they must be preserved by some method of tanning.

8. A useful method of tanning sheep skins is to use a mixture of alum, salt, and saltpetre dissolved in water containing bran.

9. If the wool is to be cleaned during tanning, soap is added.

10. To remove loose fibres and to soften the tanned skin it is rubbed with pumice stone or a piece of a brick.

11. Articles are cut from the skin by running a knife or razor blade along marks put on the leather side of the skin.

12. Tanned sheep skins can be used for making bedside mats, floor polishers, furniture dusters, boot polishers, inner-soles, powder puffs, and animal toys.

13. The most popular wool-work is the making of garments with woollen thread.

14. Garments can be knitted, crocheted, netted, or woven.

WOMEN'S BRANCHES.

PAPERS READ AT UPPER NORTH BRANCHES CONFERENCE.

[*Morchard, July 19th, 1933.*]

SESSION FOR WOMEN'S BRANCHES.

MAKING THE BEST USE OF SHEEP.

[By MRS. A. F. CUMMINGS, Belalie.]

On most farms sheep provide the main meat supply, and unless one can vary the cooking the family will get very tired of mutton every day. Some housewives serve the mutton generally as a roast with chops sometimes as a change. Then it is no wonder one hears the remark, "I am sick of mutton." There are quite a variety of ways of cooking this meat which can be made into a tasty meal besides making the most of the meat supply, a consideration in these times. Even when the farmer is his own butcher the sheep means money. The following are some of the ideas I adopt to use up the whole of the sheep whilst giving the family quite a variety of meat dishes.

The leg, shoulder, and loin are usually roasted in the oven, or braised in a boiler on the stove. If the mutton is roasted the potatoes are usually baked under the joint. The bone in a leg or shoulder may be removed and the cavity filled with seasoning. This is very nice eaten cold, and makes a nice Sunday dinner, when the "cook" should have a day's rest if possible. The leg or shoulder may be boiled with carrots or parsnips and served with either parsley or onion sauce.

The meat from neck and breast may be put through the mincer, add a little soaked bread, salt, pepper, and thyme and sausage meat will be provided for breakfast or rolls. For a small family mince one-half for sausage meat, and the rest will make a savoury stew, curry, meat or sea pie. The bones should not be thrown away but boiled to form stock for soup. The breast of mutton may be spread with seasoning, rolled and tied, then boiled or baked; it is best eaten cold. The meat from the neck makes nice Cornish pasties or small meat pies, as it is mostly lean.

The breast of mutton and knuckle end of leg or shoulder with the two kidneys will make a very nice meat pudding or pie. Allow the pudding plenty of time to cook so that the meat will be tender. The knuckle ends of a shoulder and leg and the meat from the head and the tongue will make potted meat, which is very suitable for hot days.

The sheep's head is often thrown away, but properly prepared it makes one or more nourishing meals. The head must be chopped or sawn in two; remove the eyes, tongue, and brains, then soak in salt and water for some hours. The head should be put into cold water and boiled or simmered until the meat will leave the bones. There are several ways of serving:—To make soup—Remove the head, strain, and allow to cool so that any fat may be removed, return to saucepan, add soup vegetables, and thicken with either pearl barley, macaroni, rice, or sago, serve very hot with croutons of toasted bread. The meat from the head may be cut into small pieces (also tongue and brains) and added to the soup which has been thickened with rice or pearl barley. This is sheep's head broth, and the vegetables, carrot, turnip, and onion may be put on to cook with the head, and the whole simmered for about three hours. Add a little parsley before serving.

Sheep's head fricassee may be made by cutting the meat, brains, and tongue into small pieces and adding it to white sauce; cook for a few minutes, add parsley, and serve very hot. The tongue may also be salted and boiled, and the brains fried and served on toast. Fricassee brains make a nourishing meal for an invalid.

The liver and heart should also be used. There are several ways of cooking liver; usually it is fried with rashers of bacon for breakfast. This is a favorite dish. Cut the liver into slices and place in a baking dish or casserole with rashers of bacon, then a thick layer of sliced onions, add pepper, salt, and a good dusting of flour, and nearly cover with water. Place in a hot oven and cook until tender. If a casserole is used, it may be left in the oven for the whole of the afternoon, and the long slow cooking is an improvement.

Another way is to mince the liver, bacon, and onion, put into piedish, adding a little salt, sage, and pepper. Sprinkle the top with breadcrumbs and dot with butter. Cook in a moderate oven for one hour. This is often called mock goose.

The heart should be stuffed with seasoning and roasted, and the kidneys roasted or cut in halves and fried.

Try some different ways of cooking chops; for instance, haricot chops are a change. For this take neck chops (as these are not so fat), chop in half and fry brown on both sides. Place in a saucepan. Peel and chop one onion, carrot, and turnip (grate the carrot and turnip if liked) and fry until brown. Add pepper and salt and enough flour to thicken, then add about 1 pt. of water. Stir well and pour over the chops. Allow it to stew for 1½ hours. Curried chops are also nice; these are cooked the same as the former recipe, only using an apple instead of carrot and turnip and adding curry powder with flour, pepper, salt, and sultanas. Serve with boiled rice. Chops are also nice cooked in the oven, and when partly done, pour over them a nice batter.

There are various ways of using up cold mutton left from a previous meal, which are tasty and economical. For this purpose a mincer is a boon to any housekeeper, and should be in every farm home. A very little cold mutton minced with some onion and mixed with breadcrumbs (or soaked stale bread), an egg to bind, will form rissoles for tea or breakfast, or the mince may be heated and served up on toast. The remains of a cold leg of mutton makes nice curry, which will be appreciated in cold weather.

A hash is another method of using up the remains of a leg of mutton. A casserole is nice for this, as the slow cooking in the oven does not make the meat tough. A hash or stew should never be boiled, only simmered.

Potato or shepherd's pie is always a favorite and is easily made from the left-overs of mutton. Mince some cold mutton, mix with it some chopped parsley and onion, pepper, salt, and a little flour and stock to moisten. Put into a piedish and cover with a thick layer of mashed potatoes. Brush over with beaten egg or milk and cook in the oven until it is thoroughly heated a nice brown, garnish with parsley.

This is another way for using cold meat:—1 cup of minced meat, 1 cup of bread and milk (fairly thin and previously boiled), 1 beaten egg, pepper and salt, 1 teaspoon curry powder and a little chopped onion. Mix together in a piedish. Sprinkle dry breadcrumbs on top and dot with butter. Bake from 30 to 35 minutes. Rice, breadcrumbs, potatoes, or batter may all be combined with cold mutton, making a very little into a savory and satisfying meal. The following are some recipes well worth trying:—

German Patties.—Cut thin slices of bread, and stamp out with a round cutter. Dip the rounds in melted butter. Make a mince of cold mutton, a tablespoon of grated cheese, a little curry powder, pepper and salt, and some good gravy. Thicken with a little flour. Put as much of the mixture as possible between two rounds of bread, press together, and dip in egg and breadcrumbs. Fry and serve very hot.

Mince Collops.—1½ lbs. mincemeat, 1 onion, 1 tablespoon of flour, salt, and pepper, 1 pt. water, 1 tablespoon fat. Divide the mince into small pieces and make into round balls, rolling in mixed flour, pepper and salt. Heat the fat in the saucepan and fry the balls until brown all over. When the meat is fried drain most of the fat out of the saucepan, then fry the chopped onion and add 1 dessertspoon of flour. Stir until brown, then add water; when boiling add meat balls and simmer one hour.

Meat, Macaroni and Tomatoes.—Cold meat, minced or chopped, 3ozs. macaroni, 3 large tomatoes, salt, pepper, sugar, and 1 gill of stock. Boil macaroni for 20 minutes in

salted water. Strain and place a layer of it in a greased piedish. Cover with half the meat, seasoned with pepper and salt, then a layer of sliced tomatoes sprinkled with sugar. Repeat these three layers, cover the top with breadcrumbs, and pour down the side 1 gill of stock. Bake in a moderate oven until the crumbs brown.

In summer it is advisable to put part of the sheep into pickle, as the mutton will not keep fresh in hot weather. Corned mutton is very nice boiled and served hot with carrots or cauliflower and white sauce or as a cold luncheon with lettuce salad.

The caulfat, suet, and any other scraps of fat or dripping should be rendered and put aside for soap or candles. Soap is quite simple to make at home. I generally use 12lbs. of fat at once, boiling it in the copper after the washing is done, but 6lbs. of fat can be made in a kerosene tin.

The skin of the sheep may also be used at home. Tanned or "cured" it will make a very nice mat, and odd pieces can be used to make polishers for floors, furniture, or boots. The wool, washed or "scoured," is used to make wool mattresses or wool-a-downs; it is also nice for stuffing cushions or toys for the little ones. In this way very little of this valuable animal is wasted, most of it being used up on the farm, with a small amount of labor and very little expense.

HANDMADE RUGS.

[By. MRS. E. L. ORCHARD, Belalie.]

Most of us, at one time or another, have encountered hard times, and it is then that we learn to economise. It is much better to practise economy with beauty, if possible. Patience and perseverance and a good sense of color schemes, with the use of well-worn, thoroughly clean woollen, and wool and cotton materials, can be an economy by which most of us may profit.

Wool keeps its warmth to the last thread and need not ever be wasted. Any article that can be cut into strips will make hooked or knitted rugs of almost everlasting wear.

Cotton and silk can be used, but it is not wise to mix the materials, because of their different wearing qualities. Making rugs for the floor is most fascinating work, and can be done by any member of the family—male or female—and all can help from the schoolchildren to the grandparents. Getting everyone interested is a great help, and they will love to remember that "the red in this doorslip was Norma's frock, the green was an old tablecloth the boys spilt ink on, and so spoiled for bridge; the grey was once dad's flannel trousers, that were patched at seat and knees and worn through again, &c." For this particular type of rug short ends of wool or wool and cotton goods (dressmakers' or tailors' scraps would be ideal) if knitted on a back ground of strong thread, they make wonderfully effective rugs; some authorities claim they wear longest of all home-made rugs. The idea is to knit in strips or squares, planned in striking designs and attractive colors, and they are very pleasing in effect. Twine about the thickness of knitting cotton, but of a firm twisted variety—I use macrame thread—No. 12 steel knitting needles, and a box of assorted materials arranged for convenience in separate compartments, is the necessary equipment. Cut material into pieces 2in. long by $\frac{1}{2}$ in. wide, and if the cloth is very thin, cut it wider, but same length, and fold as you work. Cashmere is cut very wide, flannel about $\frac{1}{2}$ in., and heavy cloth a little less than $\frac{1}{2}$ in.

The cutting of material into *regular* lengths is necessary for the finished appearance, and does away with any clipping afterwards. The clipping or shearing is the hardest part of your work.

The easiest way to work a rug is to knit in strips and top-sew together after knitting is finished; 13 or 15 stitches on the needle makes easy handling.

To begin: Cast on 13 stitches and knit one row, turn, knit first stitch, and lay on a piece of material a little more than half way across the thread with long end toward worker, knit second stitch, and place long end over and knit next stitch. Insert another

piece of cloth and repeat to end of row. Always work with pile of mat away from you. Knit the return row without putting in any cloth. Nine strips of this knitted fabric each as long as the rug required would make a hearthrug or bedside rug. After top-sewing the strips together, line with ticking or other firm material, and it will always keep a good shape.

Silk stockings, singlets, or any articles in Kayser or Celanese wear can be used after they are discarded by cutting into strips and crocheting into a rug.

Biscuit to brown shades make a good bedroom mat, and pink, blue, mauve, and green make a pretty bedroom cushion. When using stockings, cut off the worn feet, and beginning at the ankle, cut around the leg about $\frac{1}{2}$ in. wide, depending on the thickness each stocking will cut into a strip from 5 to 8 yards long. Wind each into a ball and arrange colors, then with a large crochet hook commence with enough chain to form centre of rug, work around with double crochet, increasing evenly at corners until size required; that makes a rectangular rug. To make an oval, increase irregularly at ends, and line with some firm material. These rugs can be cleaned by washing in Lux or soft soap, the same as if the material was still in its original form of stockings or singlets. As the feet and tops are cut off the stockings that are to be used, they can be pushed into one stockingtop and so make a soft, useful duster. I have used a rug constantly for nearly two years made from 118 stockings, 1 pair bloomers, and parts of 2 singlets, measuring $1\frac{1}{2}$ yds. by 26 in., and it is keeping the shape very well, and has not been hard to clean in spite of the northern dust. It has a flat appearance, but otherwise is showing no signs of wear.

The most fascinating of all handmade rugs is the hooked variety on canvas foundation. Many delightful designs and color schemes can be worked. Designs can be taken from the buckles on belt; patterns on linoleums are useful, and the pictures on the back of playing cards, &c.

For foundations, rug canvas or hessian can be used. Hessian is cheaper and can be used for the working of fine designs, such as flowers and for small geometrical patterns. Rug-canvas is very stiff, and open for a beginner, and the squares are easy to follow with any pattern that can be divided into corresponding squares, but it is very close work to follow the threads in hessian, though at first the canvas makes the worker's fingers tired and sore.

Hessian by the yard or cut from branbags should be washed before using for rugs to get rid of the natural unpleasant odour. All that is required to make a rug is a foundation, a No. 00 steel crochet hook, a pair of large broad-bladed scissors, and a suitable quantity of well-washed old clothes.

New materials may be used in conjunction with old, but it is best to wash and sometimes fade the materials before cutting or tearing into strips.

Generally speaking, a rug wears best if made entirely of woollen or entirely of cotton materials, though they can be mixed and a little silk or artificial silk introduced—but never in large patches—because silk tends to break away and cotton has to be treated differently to get the best results.

It is a good plan to design the rug first, and for a first attempt a simple design in lines and squares is best. When using hessian, very wide turnings must be taken or it will fray and spoil the appearance of the finished article.

When using dark material for border, it is wise to bind first of all the selvages with the same color bias binding. When the border is light, the edge is not noticed.

The next step is to cut or tear the materials into suitable widths; old material will not tear easily and goes all ways, but new is better if torn rather than cut. To test the width, hold it under the canvas, put the hook through the canvas from the top, and pull the end of the cloth through, leaving an end about 1 in. Insert the hook in the next space and draw a loop about $\frac{1}{2}$ in. to $\frac{3}{4}$ in. to the top, and if the loop fills the square comfortably without being dragged or slipped through, it is the correct width; that is all there is to learn in the stitch of hooked rugs made from cloth.

If using rug-wool, there are several ways of working a rug, all of them very beautiful. Always commence a strip with the end drawn up on to the right side and always finish a strip in the same way and commence the end of the next strip in the same space, all ends being sheared off in the final clipping of the rug. The back must be perfectly free from ends, and each loop—if the strip is of correct width—will help to keep its neighbor in place.

The last step in the making of hooked rugs is the shearing. All wool rugs are vastly improved by cutting off the surface of the loops, but cotton mats look best if left in the loops; if cut they go flat with wear, whereas the woollen materials remain soft and springy.

All clippings off rugs can be saved and used to stuff into a flock mattress or fill a cushion. They can be used in place of kapoc for filling golliwogs made from black stockings.

When shearing, only the tops of the loops need be cut, and if one occasionally is lower than others, the point of the scissors can be put in the loop and cut through. Scoured wool for rugs may be dyed with vegetable dyes.

If working a bold design, draw or stencil the pattern in colors on the canvas before commencing the hooking, and for a geometrical or conventional design it is most helpful to draw on graph paper or rule the paper into squares, to correspond with the canvas. Some of the fancywork stores in the city have designs stamped on canvas, and will stencil designs for customers, but their charges make the rug expensive. These rugs should not be lined, as they are fairly heavy and closely worked, and a lining will hold the dust. To clean them, beat against a wall and brush with a straw broom or vacuum cleaner, and if necessary sponge or wash in the usual Lux or soft-soap suds and dry in a not too strong wind.

In making the dollar rug, care must be taken to cut each piece exactly round, and if a cardboard gauge is used from which to cut each piece, the worker will find no difficulty in keeping them even.

Then there is the plaited floor rug made from cotton, silk, and artificial silk. Each color and variety of cloth is plaited separately and top sewn together and there is no need to line this type of rug, because it will wear a long time and keep flat on the floor without any backing.

If only a small quantity of material is available a good plan is to cut in $\frac{1}{2}$ in. strips, thread into a bag needle, and oversew into hessian. Mark a conventional design on the hessian in charcoal or chalk and then, taking long stitches on top and short ones underneath, sew the materials into the hessian to represent satin stitch or Indian filling in embroidery. It will make a very effective rug, and will wear satisfactorily.

[Mrs. Orchard gave a demonstration of the various methods of rug making and had on view samples of her work.]

Miss E. Campbell, Dip. Dom. Ec., Education Department, gave an address, "The Use of Wool and Sheepskins."

CONFERENCE AT COWELL.

Delegates from Women's Branches in the Eastern Eyre's Peninsula Branches met in Conference at Cowell on August 10th. Miss J. James (Mangalo), who read a paper on "Useful Hints in the Care of Sick Children," said for croup, a few drops of turpentine should be sprinkled on a piece of flannel and put around the neck. It should be left on for a few minutes according to the age of the child, and when taken off, replaced with a piece of flannel to keep the neck warm. For burns from boiling water, it was not advisable to remove the clothes, but to first pour on cold water, and after a few minutes some kerosene. If cold water was not available, use kerosene, afterwards carefully removing clothing. If done carefully no blister would appear. For other kinds of burns picric acid or lime water and olive oil was good. For centipede or scorpion bites, hot water and Condy's or washing soda was recommended. In all cases of sickness give a dose of castor oil first, or if the child cannot keep that down, a laxette. Even when a child is "teasy" and out of sorts a laxette—besides being tempting—is very useful.

In a paper in which she discussed the best way to mend men's socks, Mrs. F. Coles (Mangalo) said when a sock became much worn on the heel the best plan was to patch it. Not only was this method easier, but it was more comfortable than darns and more serviceable. First, make the hole even by trimming it with the scissors, then take from a sound yet old sock a patch just a fraction bigger than the hole in the sock. Set this in the hole and herringbone firmly all the way round. When finished, the sock looks neat and will wear like new. Toeing and heeling the socks can be done in the same way.

Miss Beryl Cleave (Mangalo) dealt with the subject of "Interesting Children in Farm Work." Children going to school, she said, thought their lessons were the worst problems in life, therefore on leaving school the children should have some object to occupy their minds because they were so free and active. A girl could be given a cow. The cow and her stock to be hers and the produce to be her mother's. She could learn quite a lot in managing a cow, milking, making butter, and rearing calves. Kindness and gentleness go a long way in handling a cow, either young or old. Regular hours for milking are most important, and as much as possible the same person should milk the same cows. The cow being the girl's very own, made her interested. Boys could be given a sheep. The first year he has its wool and the next its lamb and wool, and so on. He could eventually build up a small flock. They could also have a sow. The litters could be sold as weaners, or kept a few months and sold as baconers. There was much to learn about cows, sheep, and pigs, which made it interesting and kept the children well occupied. If they had nothing to do, there was much truth in the old saying 'Satan finds work for idle hands to do.'"

COONAWARRA.

CAKEMAKING.—Paper presented by Mrs. R. Childs:—"Most housewives have found that a cake mixed in a hurry often turns out a good one and when we want a special cake and take the most pains it will most likely be an absolute failure. But taking a general rule one must be very careful weighing and measuring the ingredients for a cake. A good pair of scales is a household necessity, and weighing is more satisfactory than measuring. Before starting to bake make sure that the fire is right; have the wood cut rather on the fine side, so that if wood has to be added while the cake is in the oven it catches quickly. It does not chill the temperature of the oven so much as heavy pieces

of wood. Cakes are divided into three classes—those made by beating the sugar and eggs together; sponges; those made by creaming the butter and sugar—coffee, ribbon, sultana, pound cakes, &c.; and those made by rubbing the butter into the flour until it is like fine breadcrumbs. This method is used for rock buns, gingerbreads, &c.; but the first two methods are the most used in cakemaking. *Making a Sponge Sandwich.*—A sponge should be beaten 20 minutes until not a grain of sugar can be felt. I always use a spiral eggbeater. A sponge needs to be beaten briskly; the one beaten in the open air is lighter than the one beaten inside. Some sponge recipes have milk in and some have boiling water. Skim milk is lighter than new milk. After beating the eggs and sugar, sift and mix lightly the dry ingredients and add lastly the water or milk. Pour the mixture into prepared tins, place carefully in the oven—preferably just a moderate oven—and do not open oven until the sponge is cooked—about 20 minutes. If the oven is opened before it will often cause sponge to flatten. There are more sponges spoilt in the baking than in the mixing. Some recipes for sponges have arrowroot or cornflour instead of plain flour with rising sifted with it, or self-raising flour. These sponges are lighter but they are not so moist nor as economical as the other sponges for general household use. A chocolate sponge is made by adding from 5 to 6 teaspoonfuls of powdered chocolate or cocoa and sifting with the dry ingredients. A spiced sandwich is made by adding 1 teaspoonful of ground ginger or cinnamon and 1 of cocoa. In testing a sponge to see if it is cooked, open the oven door carefully and touch lightly with a finger; if the sponge feels elastic to the touch and it has not left a dent on the sponge it is cooked. Remove carefully from the oven, wipe the bottom of the sandwich tin with a damp cloth, and turn carefully on to the cake cooler or a clean teatowel. The second method of making cakes is the one most used. In winter the butter is rather hard for creaming, but I find it is a good plan to place the sugar in the oven for a few minutes until it is just warm; be careful not to allow it to get too hot or it will make the butter oily. Beat together until it is a light creamy consistency, then add eggs gradually, either well beaten or separately according to recipe and beat until not a grain of sugar can be felt and the mixture is light and creamy. If making a coffee cake, sift dry ingredients gradually and mix lightly; lastly adding the milk. If making a fruit cake, have all fruit washed and cleaned and thoroughly dry. Always cut sultanas in halves—it gives the cake a finer appearance and a nicer flavor. Add fruit and flour gradually to creamed butter, sugar, and eggs, and be careful to have the mixture not too thin—this is sometimes the cause of fruit going to the bottom. Always cook fruit cakes in well papered tins, placing them in a hot oven and gradually decreasing the heat. A good way to test a fruit cake or any butter cake is to use a clean straw or hatpin, pierce the thickest part of the cake, and test if the hatpin is dry and clean. For a chocolate cake add the dry cocoa or powdered chocolate to the dry ingredients and sift twice before adding to the cake. Make three mixtures for a ribbon cake, cooking 2 pink sandwiches, 2 white, and 2 chocolate. The following recipes may be helpful:—*White Sponge.*—1 cup each sugar and flour, 1 teaspoonful tartar, $\frac{1}{2}$ teaspoonful soda, 4 eggs, 4 tablespoonfuls of warm milk. Beat sugar and eggs for 20 minutes, add flour and rising which have been sifted twice, stir in very lightly, and lastly add milk. *Rich Dark Cake.*—1½ lbs. flour, 1½ lb. butter, ½ lb. brown sugar, 1½ lb. each raisins, dates, sultanas, and currants, ½ lb. mixed peel, $\frac{1}{2}$ teaspoonful ground ginger, cinnamon, and nutmeg, 8 eggs well beaten, 1 dessertspoonful soda, ½ lb. almond kernels, and pinch of salt—a nice recipe for Christmas or wedding cake. *Ginger Fluff.*—Beat 4 eggs for a few minutes, add $\frac{1}{2}$ cup sugar and beat for quarter of an hour. Sift together three times the following ingredients:— $\frac{1}{2}$ cup arrowroot, 2 teaspoonfuls ginger, a teaspoonful cinnamon, 2 teaspoonfuls cocoa, 2 dessertspoonfuls plain flour, 1 teaspoonful tartar, and $\frac{1}{2}$ teaspoonful soda; add gently to eggs and sugar, lastly add 1 dessertspoonful golden syrup, and bake 20 minutes in two large sandwich tins. A cream filling is nice for this sandwich. *Cream Cake.*—A nice plain cake, handy to make if short of butter:—4 eggs, 1 cup each sugar and cream, 1½ cups flour, 2 teaspoonfuls tartar and $\frac{1}{2}$ teaspoonful soda. Beat eggs and sugar well together, add cream, then flour and rising which have been well sifted. Cook in moderate oven about one hour. *Walnut Cake.*—1 cup butter, 1½ cups sugar, 3 eggs, 1 teaspoonful vanilla, $\frac{1}{2}$ cup milk, 1 cup chopped walnuts, 2 cups self-raising flour. Cream butter and sugar, add well beaten eggs, then chopped nuts and flour and milk gradually. Bake 1½ hours in moderate oven. *Sultana Cake.*—8 ozs. each butter and sugar, 5 eggs well beaten, 1 small glass of sweet milk, ½ lb. of self-raising flour, ½ lb. plain flour, ½ lb. sultanas. Cream butter and sugar, add eggs, then flour and milk gradually, lastly sultanas (chopped in pieces). Bake about two hours.

RECIPES.—*Delicious Fudge Cake* (Mrs. R. Redman).—Cream $\frac{1}{2}$ cup butter and 1 cup sugar; add 1 egg and pinch of salt. Beat well, then mix in 1½ cups self-raising flour

and 1 tablespoon cocoa alternately with $\frac{1}{2}$ teaspoon soda dissolved in $\frac{1}{2}$ cup milk. Lastly add $\frac{1}{2}$ cup boiling water flavored with vanilla. Bake in moderate oven three-quarters of an hour. When cool, split in halves and join with filling:—Put into saucepan $\frac{1}{2}$ cup hot water, $\frac{1}{2}$ cup sugar, 1 dessertspoon butter. Bring to boil and thicken with 1 tablespoon cornflour and 1 dessertspoon cocoa mixed with water; can be iced if liked. *Dolly Varden Cake* (Miss O. Lear).— $\frac{1}{2}$ lb. butter, $\frac{1}{2}$ lb. sugar, 3 eggs, $\frac{1}{2}$ cup milk, $\frac{1}{2}$ lb. flour, 2 small teaspoons cream of tartar, 1 teaspoon carbonate of soda, some peel, currants, sultanas, and spice. Divide into parts; make two layers of plain mixture with fruit and spice added to the third; then bake. Place layers together with icing or jam—dark layer in the centre. *Cinnamon or Jam Roll Biscuits* (Mrs. Reschke).—2 cups flour, $\frac{1}{2}$ cup sugar, 2 eggs, $\frac{1}{2}$ cup butter, 2 teaspoons cream of tartar, 1 teaspoon soda. Cream butter and sugar, add eggs, then other ingredients. Roll out and sprinkle with cinnamon or spread with jam, then roll. Cut in pieces $\frac{1}{2}$ in. thick, dip in sugar (if preferred), and bake 15-20 minutes. *Cream Puffs* (Miss M. Reschke).—Put on to boil $\frac{1}{2}$ pint water and 2ozs. butter. When boiling quickly throw in 4ozs. flour. Stir until smooth, then take off the fire. When cool beat into the dough 4 eggs one at a time. Bake $\frac{1}{2}$ hour. *Coffee Kisses* (Mesdames Mitchell and Hoffman).— $\frac{1}{2}$ lb. self-raising flour, 4ozs. butter, 3ozs. castor sugar, 1 egg, pinch of salt, one tablespoon coffee essence. Beat butter and sugar to a cream, add beaten egg. Add essence alternately with flour-salt to make stiff dough. Place small teaspoon at a time on well-greased baking sheet. Bake 5-7 minutes in hot oven. When cool join together with 3ozs. sieved icing sugar, $1\frac{1}{2}$ ozs. butter, 1 teaspoon coffee essence. *Nut Bread* (Miss R. Hinton).—2 cups of self-raising flour, 1 cup sugar, 1 egg, 1 cup nuts, milk to mix. Beat together and half fill well-buttered tins. Bake three-quarters of an hour. *Lord Baltimore Cake* (Mrs. F. I. Skinner).—Cream $\frac{1}{2}$ cup butter and 2 cups sugar, add 5ozs. chocolate (shredded). Add 1 cup mashed potatoes, and beat well. Add 2 beaten egg yolks, $\frac{3}{4}$ cup fresh milk, $2\frac{1}{2}$ cups flour sifted with 4 teaspoons baking powder. Beat well, then add 1 cup chopped walnuts and 1 teaspoon vanilla. Fold in two stiffly beaten whites. Bake in shallow tin in moderate oven 30 minutes. Cover with thick marshmallow icing heavily tinted with saffron (gold). Mask this with thin chocolate icing (black). *Bakette Buffs* (Mrs. Modistach).—1 egg, 5 cups bakettes or crispies, $\frac{1}{2}$ cup chopped nuts, $\frac{1}{2}$ cup butter, $\frac{1}{2}$ cup sugar, $\frac{1}{2}$ cup cocoanut. Cream butter and sugar, add egg, then nuts and

cocoanut, and lastly bakettes. Put in teaspoons on greased slide. Bake until golden brown (30 minutes). Leave on tray to cool. *Raisin Shorts* (Mrs. Modistach).—6ozs. self-raising flour, 2ozs. plain flour, 2ozs. sugar, 4ozs. butter, 1 egg beaten with 1 tablespoon cold water. Rub butter into flour and sugar. Mix to light dough with liquid. Knead a little, roll out thin, and cover half with raisins or currants. Place other half on top, making a sandwich. Roll slightly in order to press together, and cut into fingers. Brush over with milk, and sprinkle with sugar and cocoanut. Bake golden brown (10 minutes). *Caramel Cake Squares* (Mrs. Len. Redman).—½lb. brown sugar, ½lb. butter, 1 egg, 1 cup self-raising flour, ½ teaspoon salt, ½ cup chopped nuts, ½ cup shredded dates, ½ teaspoon vanilla essence. Melt butter and sugar, add unbeaten egg, beat until light. Stir in flour, and beat again thoroughly. Fold in nuts, dates, and essence. Spread ½in. thick. Cook in slow oven. Cut into squares while hot, and leave in tin until cool. *Eggless Cake*.—4 cups flour, 1 cup butter, 2 cups sugar, 2 teaspoons soda, 2 teaspoons cinnamon, 1 teaspoon mixed spice, 1 cup currants, 2 cups buttermilk. Bake 1 hour. (Dripping and sour milk can be used instead of butter and buttermilk). *Christmas Cake*.—4lbs. flour, 1lb. currants, 2lbs. butter, 4lbs. sultanas, 2½lbs. sugar, 1lb. mixed peel, 2 teaspoons cream of tartar, 24 eggs, 1 teaspoon soda. Mix in ordinary way. This will make two large and two small cakes. Bake slowly from 2½-3 hours. *Delicious Cake for Tea or Dessert* (Mrs. E. Alder).—½lb. flour, ½lb. butter, ½ teaspoon baking powder, ½lb. sugar, white of 2 eggs and yolk of 1, jam. Sift flour and baking powder, rub in butter add sugar, make into stiff paste with egg yolk. Roll out to size of dinner plate. Bake a light brown. Beat whites stiff, adding sugar and essence to taste. Pile roughly on jam. Return to oven to harden. *Lamington Cake* (Miss E. Skinner).—2 cups (small) flour, 2 eggs, 1 cup sugar, 1 heaped teaspoon cream of tartar, ½ cup milk, 1 level teaspoon carbonate of soda, ½lb. butter. Beat butter and sugar to a cream. Add eggs, then flour and cream of tartar. Put soda in milk and stir in. (Secretary, Mrs. F. S. Skinner.)

KYBYBOLITE (Average annual rainfall, 22in.).

May 14th.

HOME NURSING.—Miss Kealy read the following paper:—"At some time or other sickness comes into everybody's life. It is the one legacy, unfortunately, which all will most surely inherit, therefore it is wise to be prepared. Always have a supply of bed linen and garments, well boiled old linen, and a well equipped medicine chest, containing castor oil, mag. sulph., brandy, iodine, boracic acid, and carron oil, &c. *The Selection, Preparation, and Cleaning of a Sick Room.*—It is not always convenient to choose the most fitting room for the sick person to inhabit. However, if possible, the room should be as bright and well lighted as possible, it should be well ventilated, and have a fireplace in it. Fresh flowers arranged in the room each day help to make it more cheerful.

Bed and Bedding.—Try, if possible, to avoid nursing a patient in a double bed. Feather beds are not only unhealthy, but are most uncomfortable for sick persons to lie upon on account of the great difficulty they have in preventing themselves from sinking into hollows. A good horsehair mattress is the best for a sickroom bed. With regard to pillows, suit them to each individual case; the patient will soon say how the pillows are best placed to make him comfortable. Some persons have a most happy knack of being able to place pillows very quickly and very comfortably, and one of the best pillows is so placed that the patient lies on as it were an inclined plane, and thus having plenty of support to the back of the neck and shoulders. The upper clothing should consist of a sheet, one or more blankets, according to the weather or the doctor's orders, and a thin counterpane. A draw sheet, and, in certain cases, a waterproof sheet is a necessity, more particularly in long illnesses.

Bedsore.—In all cases of long illness, a nurse will find that one great difficulty presents itself in her many duties, and that is the preventing of bedsore. Often in spite of every effort on her part a bedsore will come, and then it will be her duty to carry out every detail of treatment ordered by the doctor, because she has to prevent the nasty complication of a case from becoming worse. **Prevention.**—Always keep the parts of the body that are exposed to pressure scrupulously clean, be careful that the sheet on which the patient lies is kept smooth and free from wrinkles and bread-crumbs; remove the sheet from under the patient directly it is soiled; vary the position of patient as much as possible, and each time the patient is washed, rub well with methylated spirits, and then apply a good talc powder. If, however, a sore be established in spite of all care, the doctor should be told of it, and he will give all directions with regard to treatment.

Temperature.—Most people understand taking a temperature, the normal reading being 98.4 degrees. The armpit is the usual and best part of the body to apply the thermometer, and in doing so be careful to apply the ball next to the patient's skin, seeing that no part of the clothing intervenes.

Pulse.—It takes a great amount of experience and practice for one to understand the condition of a pulse; 70 to 76 beats a minute is the average pulse of a person lying in a horizontal position and unexcited.

Respiration.—The different kinds of respiration are of the greatest importance, about 18 to 20 respirations a minute is the average rate of breathing.

Washing a Patient.—There is nothing so refreshing to a patient as a thorough washing, and a comfortable sleep is often the result of it after restless hours have been passed.

Administration of Medicine, &c.—It is a wise rule, that instead of trusting to a spoon to measure the dose always use a marked measure glass and give the exact quantity ordered by the doctor. Fomentations are applications of hot water, and these may be simple or medicated by the addition of any drug. Always wring fomentations as dry as possible; they are more comfortable and are not likely to blister the skin.

Coughs and Colds.—How often does it happen that severe colds are caught and the seeds of life—long illnesses sown through carelessness, such as sitting about in wet clothing, or changing from woollen garments to cotton ones, &c. By taking aspirin and hot lemon drinks, and plenty of rest, a cold is sometimes checked; however, remember a cold should never be neglected. Regarding the doctor's instructions. Many persons have good memories, and many exceedingly bad ones, but even those who pride themselves upon their ability to retain what is told them so often forget; therefore, it is a good rule to have a pencil and paper at hand and make a note of all directions given by the medical man. Be loyal to the doctor under whose care you have placed the patient, and try always to carry out his orders faithfully and accurately."

BREAD MAKING.—Paper read by Mrs. John Hefferman; meeting held June 20th, 1933.—Good yeast is the first essential. Compressed yeast is very good and only takes a few hours to bake bread with it, but is rather expensive. All things being considered hop yeast is the best. **Yeast.**—Boil 1oz. hops in nine cups of water for 20 minutes, strain and add one cup each sugar and flour and mix hot. When cool, add 1½ lbs. cooked potatoes finely mashed; beat in and let rise until next morning, then add one handful salt and it is ready for use in a day. It should be put in a wide mouth jar and will not require a cover, only a clean cloth to keep out dust, &c. This yeast will keep five or six weeks and only has to be stirred before using; half a cup makes a large bake of bread. To make the bread, take five sifters of flour and add one tablespoon sugar, one handful salt, half cup yeast, and enough potato water to make into a nice dough, knead well. Cover up warmly in cold weather and leave to rise all night. Mix after the evening meal, and first thing in the morning turn it out on a floured board and work it up, taking care not to mix much flour into it, just enough to keep it from sticking to the hands; put back into the dish and let it rise again. When risen sufficiently, it rises much quicker in hot weather and does not need to be kept near the fire, take and roll into loaves. A much nicer loaf is to use 4 lb. tins and put 2 lb. loaves in them and have them greased well and again set to rise. When it is up to the top of the tins, put in a fairly hot oven and bake 1½ hours. It is a great improvement, when taking the bread from the oven, to brush over the tops of the loaves with hot water. It makes the crust nice and soft. Always stand the loaves on end, otherwise there may be a hard ridge all through the loaf. If short of bread, bake some bread rolls before the loaves are ready to put in the oven. Cut off some dough and roll into small rolls and put in a small dish; these usually rise sufficiently in half an hour, then bake about quarter of an hour. **Troubles in Bread Making.**—Once-kneaded dough is sticky and will not rise, under-kneaded dough is streaky and the bread will contain lumps of dough that have not been crushed out, too much flour gives too stiff a dough, it rises very slowly and the flavor will be poor. Too long a rising gives a porous loaf with poor flavor. If the rising continues too long, the bread settles over the side of the tin and becomes sour. Too cool an oven will make the bread rise too long and it will be porous. When putting the salt in the bread, never put it in the yeast, always put it in the flour.

RECIPES.—**Yeast or German Cake.**—Take about the same quantity of dough as for the buns and add one cup sugar, ½ lb. butter, or half butter and dripping, a little nutmeg and cinnamon, also a few currants or sultanas and three eggs. More eggs may be used if a richer cake is desired. Test well and add enough flour to make a nice soft dough; let rise for one hour and then put into a well greased meat dish or the oven slide and let rise again. Top for the cake, half cup each flour and sugar, one tablespoon butter, and a little cinnamon, crumble together, brush over the top of the cake with melted butter and then sprinkle it over. Another recipe is to brush over the top of the cake with cream or melted butter and sprinkle sugar and cinnamon over it. This is much easier; it also requires a fairly hot oven. **Buns.**—Take a piece of dough, say, 2 lbs.; after it has well risen, melt one tablespoon butter

or dripping and add one cup sugar, one egg, a few currants or sultanas, and a little nutmeg. Mix well and put in a dish to rise until the bread is put in the oven. Then turn out and work it into small buns, put on a greased slide and set to rise until the bread is baked. Bake quickly and brush over the tops with one tablespoon sugar mixed in a little boiling water and put back in the oven for a minute until the glaze dries. Caraway seeds may also be used for those that prefer them. *Raisin Bread*.—Take about 2lbs. of dough, one cup each seeded raisins and sugar, and one tablespoon dripping. Mix well, add enough flour to make into a nice dough, let rise for an hour, roll into loaves and leave to rise until ready to bake. Glaze the top with a little sugar and boiling water. (Secretary, Mrs. W. Kekwick.)

MANGALO (Average annual rainfall, 14in. to 15in.).

June 15th.—Attendance, 16.

GARDENING.—Mrs. O. Hannemann read the following paper:—"To make gardening a success a good fence, which is fowl proof, and an adequate supply of water is most necessary. If on an open spot, a breakwind should be erected. All vacant ground should be dug up, limed, and left for some weeks. Then apply a good dressing of stable manure and dig fork deep. This should again be left for some days before planting. To get early cabbage and cauliflower, sow in January and February. Sow the seeds thinly in a seed box and cover with very fine earth and a light mulch of well rotted stable manure, which should be kept moist. Once up the plants should be kept moving, giving a weak application of liquid manure once a week. Do not pour the solution on the leaves, because it will burn them. Plants do not need to be large, but strong. They should be planted 2ft. or more apart. Do not overcrowd. Choose a dull day for transplanting, and, if possible, protect them from the sun until rooted. When cauliflower heads begin to form, tie the outside leaves to protect the flower from the sun and dust. These vegetables require an abundance of water and manure. Always hoe after watering to conserve moisture. Lettuce must be grown quickly, they require very rich soil. Carrots, turnips, and all root vegetables do best on soil that has had a previous crop well manured. Seed should be sown in February or March. I prefer the Manchester Table carrot and White Stone turnip. Onions do well on sandy soil. Tomatoes need well worked ground. Never grow two crops in succession on same soil, this also applies to beans. The longer period between growing the better the results. Tomatoes do better if staked and pruned. The fruit is much larger and keeps clean. Sow the seed at the beginning of July for an early crop. Early Red Dwarf is the best variety. Epicure is a good bean. A small corner of the garden should be set aside for flowers. Roses need very little attention and flower for practically eight to nine months of the year if mulched with stable manure during hot weather and by removing all dead flowers—the cut being made to an outgrowing bud, which will very soon shoot and produce another flower. Fruit should be grown also, the value of fresh fruit cannot be over-estimated. Almond trees are profitable; they give shade and shelter, and the nuts are useful for making sweets and cakes. To eat several after each meal is very wholesome." (Secretary, Mrs. B. Coles.)

MORCHARD (Average annual rainfall, 13.59in.).

June 9th.—Attendance, 16.

INAUGURAL MEETING.—Mr. H. C. Pritchard (General Secretary) delivered an address, and the meeting then took the form of a "Question Box." Cure for turkeys with swollen heads? *Answer*.—Rub with sulphur and oil, or kerosene and oil. Put a little kerosene in drinking water, failing that pierce the head alongside the eye with sharp instrument. Tomato sauce corks "popping off"? *Answer*.—This may be caused by either the use of inferior vinegar, insufficient boiling, or because the bottles were not dry when the sauce was put into them. Which are the most profitable, spring or autumn chicks? *Answer*.—Spring chickens were favored because they would be laying at Easter, when eggs are dear. Autumn chicks do not lay until summer, when eggs are cheap. What causes home-made soap to shrink? *Answer*.—This was thought to be due to cutting up too soon. Mrs. F. Twigden always used 12lbs. fat, and when boiled it was poured into two half kerosene tins, left for three days, then turned out, and cut up after leaving in a block for three weeks.

Recipe for Furniture Polish.—Use equal parts boiled oil, kerosene, vinegar, and turpentine. Put in bottle, shake well, sprinkle on woollen cloth and rub briskly on furniture. (Secretary, Mrs. C. Schulz.)

PARILLA (Average annual rainfall, 13.90in.).

ANNUAL COOKING COMPETITION HELD ON APRIL 19TH.—The competition was opened by Mrs. H. Billing, of the Wilkswatt Branch, and was judged by Mesdames H. Fewings, F. Reze, and W. B. Davis, of the Pinnaroo Branch. The following are the sections and

prizewinners:—(1) One plain and one brown sponge, Mrs. G. Belling first, Miss Phillis second; (2) plain and brown sponge roll, Mrs. R. C. Kerley first, Miss Phillis second; (3) one sultana cake and currant cake, Mrs. Bailey first, Mrs. Welden second; (4) one seed cake and one coffee cake, Miss Heinicke first, Mrs. Smitham second; (5) ribbon cake and napoleon cake, Miss Phillis first, Mrs. Phillis second; (6) scones, plain and wholemeal, and coffee rolls, Mrs. Colwill first, Mrs. Bailey second; (7) nut loaves, Mrs. Johnston first, Mrs. Phillis second; (8) cream puffs, Mrs. Dabinett first, Mrs. Wright second; (9) puff pastry, Mrs. Brown first, Mrs. Colwill second; (10) collection of biscuits, Mrs. Howie first and special, Mrs. R. C. Kerley second; (11) plate of small cakes, Mrs. R. C. Kerley first, Mrs. Phillis second; (12) bread (white and wholemeal and bread rolls), Miss Phillis first and special, Mrs. Phillis second; (13) yeast cake, Miss Phillis first, Mrs. Phillis second; (14) rich dark cake, Miss Colwill first and special, Mrs. Welden second; (15) six jars jam, Mrs. Foale first and special, Mrs. Colwill second; (16) three jars jelly, Mrs. Foale first, Mrs. Pearce second; (17) one lemon marmalade and one orange marmalade, Mrs. Foale first, Miss Colwill second; (18) three bottles preserved fruit, Miss Colwill first, Mrs. R. C. Kerley second; (19) tomato sauce, Mrs. F. Kerley first, Mrs. Foale second; (20) cucumber pickle, Mrs. F. Kerley first, Mrs. Foale second. The competition was held in the afternoon, and in the evening a dance was held, when the hall was crowded, showing the popularity of the Women's Branch of the Agricultural Bureau. (Secretary, Mrs. R. Welden).

PARRAKIE (Average annual rainfall, 14.49in.).

June 27th.—Attendance, 15.

KNITTING.—Mrs. M. Cabot read the following paper:—"Knitting has many advantages over other 'fancy work,' in that it is quickly done, easy to do, very little eye-strain, and it can be done anywhere at any time when one has a spare moment. During the War many people learned to knit, principally to make garments and comforts for the soldiers, but after the War was over the knitting needles were put away, only a few mothers retaining them to knit socks for husband or sons. A few years ago when the price of wool became so low, everyone was urged to 'use more wool' to assist the wool-growers. Knitting wools were manufactured in numberless shades and sizes, and then it became fashionable to wear knitted garments. The result was that nearly every person learned to knit. The colorings of the wool are dainty and the patterns of garments interesting and varied. The knitting craze has been a great boon to sheep farmers, and the price of wool at the present moment is higher than it has been for some time. In knitting there are only two stitches—plain and purl—and it is just a matter of how they are put in order that makes the pattern. Anyone who has achieved the art of knitting by following any instructions given should be able to accomplish any garment. A few of the best known stitches are garter stitch, stocking stitch, moss stitch, pineapple stitch, and cable stitch. *Knitting Hints.*—When pressing woollens, always press on wrong side over a damp cloth with a hot iron. When knitting socks, shrink the wool before knitting. Take the skein, soak it in lukewarm water for a few minutes, squeeze out the water, and lay out on paper to dry. When dry, wind loosely. To join the edges of a knitted garment, lay the two portions of the work to be joined on a flat surface so that the edges just touch and catch the corresponding edges together, taking a stitch first from one side and then from the other, on the side nearest to you; point the needle towards you when taking the stitch and on the far side of the work, point the needle away from you. From one side always lift the lower stitch of the ridge, while on the other side lift the top stitch. Do not draw the thread tight. When joined in this way, the seam is almost invisible. When joining wool, never make a knot; always splice the two ends. Persons who suffer from rheumatism should always use bone knitting needles; steel needles are very cold. When washing woollens, never rub—squeeze the article to be washed in lukewarm water to which Lux has been added. Rinse in water of the same temperature, and squeeze out the water. Spread out on paper to dry after having pulled the article into shape."

KNITTING.—Paper read by Miss I. Coleman:—"When rolling a skein of wool, a good plan is to roll it around a block of camphor and there will be no danger of damage by moths. Do not roll tightly; this stretches the wool. Do not knit tightly, as this spoils the appearance of the work. When casting off the back of a jumper to shape it, knit row until five stitches remain on each end, then knit back until 10 stitches are on both ends, and so on until there are about 3in. left, then knit to end of row and cast off. Always cast off in purl; this allows the work to stretch. Always knit into back of all cast-on stitches, to form a neat and strong edge. To make a stitch, bring wool forward between needles and over the right hand needle. Some jumpers are shown to better advantage if not ironed. To iron a jumper, press carefully under a damp cloth and use a hot iron." (Secretary, Miss J. Halliday.)

PENOLA (Average annual rainfall, 26.06in.).

June 7th.—Present: 29 members.

RECIPES FOR CAKES AND BISCUITS.—The following were supplied:—*Dark Rich Cake* (Mrs. Carne).—1lb. flour, ½lb. self-raising flour, ½ grated nutmeg, ½ teaspoon salt, 1 teaspoon cinnamon, ½ teaspoon spice, 8 eggs, 1lb. each butter and castor or soft sugar, 1½lbs. sultanas, 1lb. currants, ½lb. raisins, ½lb. each dates and candied peel, 2 table-spoons brandy, 1 saltspoon soda stirred in 1 dessertspoon boiling water. Divide into two tins and bake 2½ to 3 hours. Test with dry straw. *Soone Loaf*.—Sift 3 cups flour with 2 teaspoons cream of tartar and 1 teaspoon carbonate of soda, pinch salt, 1 teaspoon cinnamon or mixed spice, 1 cup mixed fruit, ½ cup sugar, stir in 1 table-spoon melted butter, sufficient milk as for fruit cake. Turn into buttered tin, and cook in a moderate oven for 1½ hours. Slice and butter for use. Improves a few days old. *Melting Moments*.—½lb. butter, 3 tablespoons each icing sugar and cornflour, 9 tablespoons flour; beat butter, add icing sugar, beat these well, add the cornflour and lastly flour; take small pieces and roll between the hands. If inclined to stick, corn-flour hands. Place on cold slide and mark with a fork or force through a biscuit forcer. *Jewish Cake* (Mrs. Levick).—½lb. butter, ½lb. sugar, 1 dessertspoon cinnamon, 3 eggs, ½lb. S.R. flour, ½ cup milk and water. Method.—Beat butter and sugar to a cream, add eggs, well beaten, then flour and cinnamon sifted together; lastly milk and water. Bake in sandwich tins about 20 minutes. *Caramel Icing*.—2 cups light brown sugar, 1 dessertspoon butter, ½ cup milk, pinch of c. tartar; boil together 12 minutes; when cold beat to a cream and add vanilla essence. If too thick, add a little milk. *Cocoanut Square* (Mrs. Provis).—3ozs. each sugar and butter, 6ozs. S.R. flour, 1 beaten egg. Rub sugar, butter, and flour together, add egg. Press out on baking dish and spread lightly with jam, put in moderate oven. Mix 1 cup each sugar and cocoanut and 1 beaten egg; sprinkle lightly on top of cake and bake until golden brown. *Savory Chops* (Mrs. C. Reilly).—Trim as many chops as required of all fat, and roll them in plenty of flour. Lay in a casserole or pie dish and sprinkle with salt and sugar. Mix in a basin 3 tablespoons tomato sauce, 2 tablespoons each Worcestershire sauce and vinegar and sufficient water to cover chops. Cover dish and cook slowly for 2 hours. *Savory Pudding* (Mrs. Thos. Kidman).—½ cup flour, 1 cup suet or dripping, 1 onion, carrot, parsnip, turnip, and potato, 2 teaspoons c. tartar, 1carb. soda, pepper and salt to taste, a little mixed herbs and 1lb. minced meat. Mix as for plum pudding and put in cloth and cook 4 hours. If fresh meat is used, keep water boiling well. *Ginger Cake* (Mrs. J. Neilson).—2 cups flour, 1 small cup sugar, 2 tablespoons treacle, ½ cup milk, ½lb. butter, 1 teaspoon each mixed spice, cinnamon, 2 of ginger, 3 eggs. Beat butter and sugar together, add treacle, then eggs, beat short time. Mix dry ingredients. Dissolve 1 teaspoon carb. soda in milk and add lastly. Put a few pieces of butter on top and sprinkle with cocoanut and sugar. *Useful Cake* (Mrs. W. Balnaves).—½lb. butter, 1 cup sugar, 2 eggs, 1 small cup milk, 2 teaspoons c. tartar, 1 carb. soda. Cream butter and sugar, add egg (beaten), then milk, with soda and c. tartar. Add currants or cocoanut. *Caramel Rhubarb Pudding* (Mrs. W. L. Redman).—Mix together 2ozs. each butter and sugar, spread inside a basin. Make a crust with ½lb. flour and 3ozs. dripping, 1 teaspoon baking powder, and pinch salt, mix with cold water to make a stiff dough. Line basin carefully with paste, reserving enough for lid. Fill mould with cut-up rhubarb and 4 tablespoons sugar, wet edges well, put on lid. Tie greased paper on top and steam 2 hours. *Cinnamon Cakes* (Mrs. J. Doman).—1 cup sugar, 3½ cups flour, 1 cup golden syrup or honey, ½lb. dripping, 2 teaspoons c. tartar and 1 of carb. soda, ½ cup milk. Mix dripping and sugar with 2 tablespoons boiling water, then add golden syrup, then flour, with c. tartar and soda added, lastly milk. Roll into balls with hand and dip into cinnamon and sugar. Bake on greased tray. These cakes improve with keeping. *Dark Fruit Cake* (Miss K. Sharam).—½lb. butter, 1 cup each sugar, S.R. and plain flour, 1 cup milk, 2 eggs, ½lb. each currants and sultanas, 1 tea-spoon soda, lemon peel, ½ nutmeg, ½ teaspoon spice, 2 tablespoons jam. Mix butter and sugar, add eggs, milk, and flour, jam last. *Cornflake Dainties* (Mrs. Mitchell).—Beat whites of 2 eggs with ½ cup sugar, add 1 teaspoon vanilla, ½ cup cocoanut, 2 cups cornflakes, mix all together. Melt 3ozs. butter and mix. Drop teaspoonful on slide. Bake in cool oven about ¼ hour. If liked, an almond on top. *Teddy Bear Cake* (Mrs. J. McCalman).—2 tablespoonfuls butter, 1 cup sugar, ½ cup milk, 5 eggs, 2 cups flour, essence of lemon or vanilla. Beat butter and sugar to a cream, add eggs and beat well. Then add milk and essence. Lastly, add S.R. flour and beat for 10 minutes. Bake for ¼ hour in a hot oven. *Rough Cake*.—4 cups flour, 2 cups sugar, 2 eggs, 1 cup dripping, 1½ cups milk and a few currants or other fruits, 2 teaspoonfuls cream of tartar, 1 of soda. Warm, but do not oil the dripping, and beat it with the sugar. Add eggs and then milk. Finally put in the other ingredients. *Cocoanut Crispies* (Mrs. T. Oswald).—2 cups rolled oats, 2 tablespoonfuls golden syrup, 1 cup flour, 6ozs. butter, 1 cup each sugar and cocoanuts, 1 small teaspoonful vanilla essence, 1 tea-

spoonful soda dissolved in three tablespoonfuls hot water. Mix butter and sugar, add syrup, then soda in hot water, rolled oats, cocoanut, and flour. Take about a teaspoonful of mixture, drop on tray; bake in a very slow oven. *Date and Nut Slices* (Mrs. R. Milway).— $\frac{1}{2}$ cup butter (equal $\frac{1}{2}$ lb.), 1 cup sugar, 1 egg, 2 cups each chopped dates and flour, 2 teaspoonfuls baking powder, $\frac{1}{2}$ teaspoonful vanilla, $\frac{1}{2}$ cup chopped walnuts, $\frac{1}{2}$ cup milk. If possible buy stoned dates—they are more economical. Sift flour, baking powder, and salt, add sugar, and rub in butter. Mix stiffly with beaten egg and milk. Turn on to a floured board and roll out into a large square $\frac{1}{4}$ in. thick. Mix dates and walnuts together; add tablespoonful boiling water and beat until soft. Spread over half mixture and fold other piece over the top; press down edges. Put on greased slide or oven tray and glaze top with milk or beaten egg. Bake in quick oven until golden brown. Cut off into squares or strips while hot; suggested size is 1 in. x 2 in. Raisins, sultanas, or figs may be used. Omit boiling water if using these fruits. *Butter Cake* (Mrs. W. Mitchell).— $\frac{1}{2}$ lb. butter, 6ozs. sugar, 9ozs. flour, 1 teaspoonful soda, 2 cream of tartar, 3 eggs, 3 tablespoonfuls milk. Beat butter and sugar, add eggs, and then flour. I sometimes use cocoa (2 small teaspoonfuls) or 2 tablespoonfuls coffee essence, with walnuts added. Bake about $\frac{1}{2}$ hour. *Jubilee Cake*.— $\frac{1}{2}$ cups S.R. flour, 1 tablespoonful castor sugar, 1 dessertspoonful butter, 1 cup each sultanas, currants, and peel, 1 egg, $\frac{1}{2}$ cup milk, pinch of salt. Mix dry ingredients together, add eggs and milk; while still hot pour over 2 tablespoonfuls icing sugar mixed with milk, sprinkle with cocoanut; bake $\frac{1}{2}$ hour. *Cream Puffs* (Mrs. Beschke).—Put $\frac{1}{2}$ pint water and 2ozs. butter on to boil. When boiling, throw in quickly 4ozs. flour. Stir until smooth, then take off fire. When cool, beat into the dough 4 eggs (one at a time). Bake for $\frac{1}{2}$ hour. (Secretary, Mrs. E. Kidman.)

PINNAROO (Average annual rainfall, 14.54 in.).

May 5th.—Attendance, 28.

The meeting was held at the residence of Miss K. O'Loughlin, who gave a demonstration of wholemeal cookery and read the following recipes:—*Wholemeal Bread*.—2 qts. wholemeal, 2 qts. plain flour, pinch of salt, $\frac{1}{2}$ cup treacle, 3 cups yeast, enough warm water to make a fairly moist dough, and allow to rise in the usual way. *Wholemeal Scones*.—3 cups each S.R. flour and wholemeal, pinch of salt, 1 dessert-

Head Office: MELBOURNE.

spoonful treacle. Add treacle to buttermilk or milk and mix fairly moist. *Marmalade Pudding*.—1½ cups wholemeal, ¼ cup marmalade, 1 tablespoonful butter, 1 teaspoonful soda in ¼ pt. of milk. Boil 4 hours; fill basin three-quarters full. *Fruit Cake*.—½lb. wholemeal, ½lb. each sugar and butter, 5 eggs, ½ cup each treacle and strong black coffee, 1 teaspoonful each carbonate soda and mixed spice, ½lb. each currants and raisins (stoned), 2ozs. each dates and lemon peel, juice and rind of ½ lemon. *Wholemeal Biscuits*.—½lb. each wholemeal, flour, butter, and sugar, 3 eggs, 1 teaspoonful carbonate soda and 2 teaspoonfuls cream of tartar, ½ cup milk or buttermilk. *Cream Biscuits*.—1 cup cream, ½ cup sugar, 3 eggs, 3 cups wholemeal, 1 teaspoonful carbonate soda and 2 of cream of tartar. *Wholemeal Buns*.—½ cup each wholemeal and flour, ½ cup each treacle, sugar, and milk, 1 teaspoonful each ginger, cinnamon, and ½ teaspoonful soda dissolved in little boiling water. Bake in moderate oven in papers. When cold, fill centres with whipped cream. *Ginger Nuts*.—½lb. wholemeal, ½lb. each treacle and butter, ½oz. ginger, spice to taste, 1 teaspoonful carbonate soda, ½ teaspoonful salt, 3ozs. dark sugar, 2 tablespoonfuls milk. *Cream Cakes*.—1 cup cream, ½ cup sugar, 3 eggs, 2 cups wholemeal, 1 teaspoonful soda and 2 of cream of tartar. Bake in patty papers; when cold, lift a centre and fill with whipped cream. *Ginger Pudding*.—2 cups wholemeal, ½ cup each treacle and butter, 1 teaspoonful each ginger and cinnamon, ½ cup of milk, 1 teaspoonful soda, pinch salt. Boil 4 hours; serve with sauce. *Parkin*.—½lb. wholemeal, ½lb. plain flour, ½lb. butter, ½lb. brown sugar, ½oz. ground ginger, ½ teaspoonful carbonate soda, ½lb. golden syrup, 1 egg, and enough warm milk to mix. Bake in flat dish. Wholemeal cooking requires to be mixed fairly moist, otherwise it is inclined to be dry when cooked and crumble. Recipes with treacle or honey are generally good for wholemeal. It also makes an excellent porridge. Boil for ½ hour and when cooked whisk with eggbeater. (Secretary, Mrs. F. Atze.)

June 2nd.—Present: 20 members.

HOME NURSING.—Mrs. J. Fisk read the following paper:—"When time and circumstances permit choose a bright, sunny room, and remove all unnecessary furniture, carpets, &c. This will prove a great help in keeping the room clean and tidy, especially if it is necessary to disinfect afterwards. A single bed will be found to be most convenient. Arrange the bed so that it is in such a position that it is not in a draught and the occupant can see out of the window. This will be much appreciated when the patient is convalescent. A horsehair mattress will be found the easiest on which to nurse the sufferer, and may be protected by layers of newspaper if no mackintoshes are procurable. After the long sheet has been placed over the mattress a draw sheet arranged across the bed, under which the mackintosh or protective newspaper is put, will save linen and prevent unnecessary moving if the patient is unconscious. A long sheet folded in halves will serve as a draw sheet. If the patient is helpless always secure aid when lifting or moving him, as if this is attempted single handed the patient is forced to exert himself, which will probably be very harmful. He should be sponged once a day at least, particular attention being paid to the back. If the illness is prolonged methylated spirits applied to the back and the presence of a soft pillow will greatly alleviate this complication. Any crumbs should be removed from the bed after each meal, and the sheet kept straight and free from creases. If the patient has long hair, keep it in two plaits. Remember that little things irritate sick people, so do not burden him with long conversation, wear slippers or shoes with rubber heels, and keep the rest of the household as quiet as possible. Any flowers should be removed from the sick room at night. Reassure the patient and keep his spirits bright, and refrain from discussing depressing subjects with him. Provide him with some means of attracting attention when required, such as a bell. Ventilation to be thorough must be systematic. It is the frequent changes of temperature which do harm, the sudden alteration between hot and cold which must be carefully guarded against and prevented. Always keep window open at top day and night; the stale used-up air rises and goes out of the top of the window, fresh air comes in through the opening at the bottom. Always close window and door when the patient is being sponged or examined by doctor. If the patient is too weak to clean his teeth put a piece of lint around the handle of the toothbrush and clean teeth and gums. A good mouth wash is made with glycerine and lemon juice. *Burns*.—Always keep a bottle of carron oil or picric acid in the house. Soak the lint or soft rag, apply to burns, and cover affected part up as soon as possible. Carbonate of soda may be used in the same way. If burns are severe it is advisable to call in the doctor. *Infectious Diseases*.—Keep patient isolated. All bed and body linen of patient should be placed in a bucket containing disinfectant before leaving the room. The food which has been in an infected room must be destroyed, the crockery boiled, and all bedding boiled and bed disinfected. Always use a damp disinfected duster in infectious cases, and wash the floor each day with

disinfectant. Do not sweep with a broom. Never delay in calling in the doctor where there is a persistent temperature. Many a life has been lost through this neglect. Food is essential to keep the body in good health. It is needed to keep up heat as well as to maintain muscular and brain power. If a person is starved he loses not only weight but vitality, the capability of doing physical or mental work, and the temperature falls. When people are ill food is even more essential. It must be both digestible and nutritious. Punctuality in giving nourishment and medicine is always important. Never ask a patient what he would like to eat. Serve food in a dainty manner and a little at a time. Remember—"Prevention is better than cure'."—(Secretary, Mrs. Atze).

RENDELSHAM.

June 7th.—Attendance, 12.

BISCUIT MAKING.—Mrs. Bignell read the following paper:—"It is a good plan to give one whole day to biscuit making. It is rather tiring work, so if several different kinds are made that day and stored in airtight tins it will only be necessary to make biscuits every few weeks. Biscuits put away in tins for a few days before using are much nicer than newly made ones. A moderately hot oven is needed. Clean slides and grease before using with dripping—butter creates moisture. When biscuits are cooked tilt on to flat trays or boards until first heat is gone. Wash bowls, beaters, spoons, &c., after each mixture is completed. Flavored icings improve plain biscuits; while rich biscuits are nice with a sharp jam put between, or on top, then dipped in cocoanut. *Anzac Biscuits.*—1 cup each of S.R. flour, flaked oats, cocoanut, and sugar. Melt in a saucepan $\frac{1}{2}$ cup butter 2 tablespoons water, 1 tablespoon treacle, 1 teaspoon soda. When thoroughly heated add the dry ingredients and drop in small spoonfuls on greased tray; bake 15 to 20 minutes in medium oven. *Oaties.*— $\frac{1}{2}$ cup sugar, $\frac{1}{2}$ cup butter, beat together and add 1 cup flaked oats, $\frac{1}{2}$ cup plain flour, $\frac{1}{2}$ teaspoon carb. soda dissolved in tablespoon boiling water. Mix well and drop small spoonfuls on greased tray; bake in cool oven; stand on tray a few minutes when cooked. *Nut Biscuits.*—Rub $\frac{1}{2}$ lb. butter into $\frac{1}{2}$ lb. flour with which has been sifted 2ozs. castor sugar and 1 teaspoon baking powder. Mix into stiff dough with the yolk of 1 egg and 1 tablespoon cold water. Roll out thin. Mix 5 tablespoons icing sugar (rolled) with the lightly beaten white of 1 egg, spread on dough, sprinkle with chopped nuts, and cut into fingers. Bake in oven moderate at first then somewhat cooler. *Raspberry Sandwich Biscuits.*—4 cups flour, $1\frac{1}{2}$ cups sugar, $\frac{1}{2}$ lb. butter, 3 eggs, 2 teaspoons c. tartar, 1 teaspoon soda. Roll out thinly, cut, and bake in quick oven. Spread jam between while hot. Bake 5 to 10 minutes. *Macaroons.*— $\frac{1}{2}$ lb. butter, $\frac{1}{2}$ lb. flour, $\frac{1}{2}$ lb. sugar, 1 teaspoon each baking powder and essence of vanilla, 2 eggs. Beat butter and sugar, add other ingredients. Make into small balls and put an almond on top of each. Bake 10 to 15 minutes in moderate oven. *A Light Biscuit.*—1 lb. flour, $\frac{1}{2}$ lb. butter, $\frac{1}{2}$ lb. sugar, 2 eggs, 1 teaspoon baking powder. From this recipe one can make a variety of biscuits by different fillings, icings, &c. *Honey Biscuits.*—1 lb. flour, $1\frac{1}{2}$ lbs. honey, 4 eggs, 4 teaspoons soda, 2 teaspoons mixed spice, $1\frac{1}{2}$ nutmegs, flour enough to roll out, a few drops of essence of lemon and a little ginger if liked. *Hunting Nuts.*—1 sifter of flour, put into flour 1 teaspoon each ginger, cinnamon, and soda. Sift these into bowl, add 1 cup brown sugar and $\frac{1}{2}$ lb. dripping, rub dripping into dry ingredients, then add 2 eggs. Have 1 lb. treacle warmed and add a little at a time. If desired cakey put white sugar, and let stand 4 hours; roll into round balls and bake in moderate oven. *Poor Man's Biscuits.*—8 cups flour, 4 level cups sugar, $1\frac{1}{2}$ cups milk, 3 teaspoons soda, 2 teaspoons c. tartar, 3 cups dripping, pinch salt, flavoring to taste, and boil milk and sugar, sift in soda; pour over flour, &c.; when cool roll out thin and bake. These biscuits will keep fresh any length of time if kept in air-tight tins." (Secretary, Mrs. G. Andrews.)

TANTANOOLA.

June 7th.—Attendance, 13.

DRY SALTING A PIG.—Mrs. E. Telfer (Hon. Secretary) read the following paper:—"The best months for curing a pig are May, June, July, August. After the pig has been cut in suitable pieces, remove the ham bone, insert a few holes in the thick part of the hams with a steel, and work some salt and saltpetre into the hole with the steel. Then rub the pieces well with coarse salt and stack them, flesh side up. After two days change the position, putting the bottom pieces at the top after rubbing with a mixture made up of the following: 3lbs. brown sugar, 7lbs. salt, 2ozs. saltpetre, 1oz. allspice, 1 dessertspoon of carb. soda. This mixture will cure 1cwt. of meat. Rub the pieces twice a week, each time changing the position. Leave the sides in a fortnight and the hams 3 weeks. Wash in luke-warm water and hang to dry, then smoke. Afterwards rub over with olive oil."

BRINE FOR CURING PORK OR BEEF.—Recipe supplied by Mrs. Altschwager:—"1 gall. water, 1½ lbs. salt, ½ lb. brown sugar, ½ oz. potash. *Method.*—Boil and skim, then cool, when cold pour over the meat. The meat must be thoroughly cold and well sprinkled with crushed saltpetre to remove the surface blood. The above proportion to be used in making any quantity. Float a raw potato or an egg to test the strength of the brine." (Secretary, E. Telfer.)

WARCOWIE (Average annual rainfall, 11.42 in.).

June 6th.—Attendance, 8.

JAM MAKING.—Paper read by Miss G. Sanders:—"Select fruit that is firm and sound, fruit that is over-ripe is more likely to ferment or develop mould. Jam should be boiled in a shallow enamelled preserving pan, using a large wooden spoon for stirring. If boiled quickly it gives the jam a better flavor and a brighter color, while insufficient cooking causes fermentation. ½ lb. sugar to every 1 lb. of fruit is quite sufficient if the jam is to be used right away, should the fruit contain acid, 1 lb. sugar to every 1 lb. of fruit may be used. If a tablespoon of butter is added to jam when cooled it brings all stones to the surface, makes it clearer, and does not injure the jam in any way. *Recipes.*—*Apricot Jam:* 12 lbs. apricots, 12 lbs. sugar, 4 cups water, 1 teaspoon tartaric acid. Boil sugar and water a few minutes, remove scum, then add apricots, which have been halved and stoned. Add a few kernels and boil quickly for 1 hour, add acid just before the jam is cooked. *Melon and Lemon:* Cut 7½ lbs. melon into pieces, sprinkle 7½ lbs. of sugar and stand all night. Cut 6 lemons in slices, cover with boiling water and stand all night. In morning, boil all together." (Secretary, Mrs. A. Crossman.)

YURGO.

June 14th.—Attendance, 9.

PRESERVING FRUIT.—Paper read by Mrs. Sanders:—"Syrup for fruit preserving is prepared by making a solution of ½ lb. of sugar dissolved in 1 pint of water. Boil and set aside to cool. Select only sound and firm fruits. Have all fruit as near one size as possible and pack very closely in jars without bruising. Pour over syrup to cover fruit, and place in steriliser with water reaching to within 1 in. of top of bottles. The best kind of bottles are those sealed by vacuum and are very strong. I have had no trouble with those, and they are not very expensive. The rubber rings with care will last two or three seasons. Different kinds of fruit need different temperatures. The harder fruits need longer cooking with higher temperatures. My steriliser was made at home from a 5-gall. oil drum which holds 8 large bottles, leaving the lid to fit down over the bottom half. It is rather cumbersome, but answers the purpose. A kerosene tin cut in halves lengthways can also be used, but does not hold so many jars." (Secretary, Mrs. R. Sanders.)

[**ERRATUM.**—The recipe for polish for stained floors on page 1314, June issue, should read—1 bottle of methylated spirits, instead of kerosene.—Ed.]

MISCELLANEOUS.

Agricultural Bureau Conferences.

Branches of the Agricultural Bureau have been advised that District Conferences will be held as follows:—

Eyre's Peninsula (Southern), at Cummins, Wednesday, October 4th. (Secretary, Mr. H. M. Roberts.)

Eyre's Peninsula (Central), at Minnipa, Friday, October 6th. (Secretary, Mr. D. V. Kitto.)

Each Conference will commence at 10.30 a.m.

Retirement of Mr. C. H. Beaumont.

Orchardists in the Southern districts regret to learn of the recent retirement of Mr. C. H. Beaumont, who for many years so ably filled the position of District Horticultural Instructor, and who was a constant contributor to this *Journal*. He was born in Ballarat, Victoria, and was educated as a mining engineer, taking chemistry and botany as part of the course. His first appointment was that of an analyst at Broken Hill, and later he went to Western Australia as a mine manager; he returned to Broken Hill as general manager of the Junction Mine, but he was compelled to retire owing to the effect of gases from a fire which had broken out there. He established a home at Penwortham, where he planted an extensive orchard and conducted experiments for the Department of Agriculture on the control of codlin moth. After disposing of his orchard he came to Adelaide and joined the horticultural branch as an inspector, and for a while was attached to the staff at the Blackwood Orchard.

In 1914 Mr. Beaumont travelled to South Africa and England, and presented a report on the marketing of South Australian fruits. Some 10 years later he went to Canada and California in order to obtain information on the export of fresh fruits and on methods of drying and handling grapes and prunes. The introduction of insecticides in dust form is to Mr. Beaumont's credit, and he was the first to point out the importance of chlorate of soda as a weedicide. Dehydration has been a pet subject of Mr. Beaumont, and the establishment of many plants now in use is largely due to his advocacy. Zealous attention to his duties as District Horticultural Instructor has been highly appreciated by fruit and vegetable growers and by Branches of the Agricultural Bureau in the district which was under his supervision. Besides a special vote of appreciation carried at the recent Southern Conference, Mr. Beaumont has received many letters from Branches and others expressing the high esteem in which orchardists of his district regard the services which he has rendered to them.

Feeding Value of Malt Coombs.

Farrell's Flat asks, "What is the feeding value of malt coombs?" Replying to the question, Mr. W. J. Spafford, Deputy Director of Agriculture, says South Australian malt coombs have been analysed fairly recently with the following results, and they are presented alongside of those of wheat bran, to which foodstuff the coombs are comparable:—

	Malt Coombs.		Wheat Bran.	
	Composition. Per Cent.	Digestible Nutrients. Per Cent.	Composition. Per Cent.	Digestible. Nutrients. Per Cent.
Moisture	12.2	—	12.2	—
Ash	5.6	—	3.6	—
Crude protein	21.0	16.8	16.4	13.0
Fat	1.2	0.9	2.6	1.8
Nitrogen-free extracts	42.3	30.9	56.8	40.3
Fibre	17.7	9.8	8.4	2.2
Starch equivalent	43.8		45.1	
Nutrient ratio	1 to 2.5		1 to 3.6	

Extra Power *means*
Money Saved
in taking off the crop

With
VOCO
POWER
Kerosene

and
Mobiloil
REGD.
the one oil that always
stands up

These figures show that bran with a starch equivalent of 45.1 per cent. is a little better fattening foodstuff than is malt coombs with 43.8 per cent. of starch equivalent, but on the other hand the high digestible protein content of 16.8 per cent. for the coombs and the narrow nutrient ratio of 1 to 2.5 makes it a better foodstuff for the production of milk and the growth of young animals than is bran with a digestible protein content of 13.0 per cent. and a nutrient ratio of 1 to 3.6.

Because of its mechanical condition, as well as because of its concentrated nature as a foodstuff, malt coombs can be fed to sheep or cows to best advantage if mixed with hay chaff. If for any special reason sheep were to be kept off pastures and were wholly artificially fed with hay chaff and malt coombs they would need to receive from 1½ lbs. to 1¾ lbs. chaff and from ½ lb. to ¾ lb. malt coombs. Such a happening, however, would be of rare occurrence, and when ordinary sheep are hand fed it is usually done to supplement failing pastures, and for the purpose a mixture consisting of ¾ lb. to 1 lb. of chaff and 4 ozs. to 6 ozs. of malt coombs should prove useful. For milking cows, where malt coombs is the only concentrated foodstuff available, it should be given in hay chaff at the rate of about 1 lb. for every 4 lbs. of milk being produced by the animals. Better results, however, are likely to be secured if malt coombs is given in a fifty-fifty admixture with bran or oats rather than as a single concentrate.

VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers, Stock and Brands Department.]

Southern Conference: "Is information available of the health of pure-bred stock as compared with grade cows, under the same conditions, or can any evidence be given as, for instance, are pure-bred stock more susceptible to mammitis, abortion, milk fever, or hoven than herd cows?"

Reply—Pure-bred stock are no more susceptible to any of these diseases than grade or ordinary herd cows. Milk fever only occurs in high producing animals, but will affect them irrespective of their breeding. Again, with mammitis, contagious abortion, and hoven if you expose your animals to the causes that give rise to these troubles they will contract them with equal facility, no matter what their breeding may be.

Southern Conference: "Is contagious abortion more prevalent in dairy herds in South Australia than is generally thought?"

Reply—This disease is undoubtedly more prevalent in dairy cattle in this State than is commonly thought. In the first place, when a case of abortion occurs in their herd, many owners are prone to think that the trouble is merely due to some "accidental" cause. It is only if they get a succession of cases perhaps that they begin to realise that the contagious form of the disease is present. While it is true that abortion in cows can occur as the result of accident, rough handling, &c., such cases are ever so much less common than is generally thought. It can safely be said that over 90 per cent. of cases of abortion that occur in cows are due to infection with the contagious disease, and the wisest policy to adopt is to treat every case as contagious until definite proof to the contrary can be obtained. Then, again, abortions not infrequently occur in the early stages of pregnancy (and this is especially the case in heifers) and pass unnoticed. The first sign of anything being wrong is the animal "coming in season" again after she was thought to be safely in calf. This is usually considered to be merely a "failure to breed," and so the animal is put

straight back to the bull again. No suspicion is raised that she might be affected with contagious abortion, as is often the case. It would be wise for owners to "check up" more thoroughly on such cases of apparent failure to breed.

Southern Conference: "Does contagious abortion take different forms with cattle?"

Reply—There is only one actual form of the disease, though the clinical manifestations may vary somewhat in different animals. The usual evidence of infection is the occurrence of abortion, especially if the infection is recent. Some few animals, however, never abort at any time, and so are never suspected of being infected. Yet they can spread the disease to other animals. After a cow has aborted once or perhaps twice, she will subsequently carry most if not all of her calves to full term and calve apparently normally, although she is still an infected animal. In the majority of cases, however, the membranes or "afterbirth" will be retained, and an evil-smelling, dirty discharge from the uterus persists for some weeks.

Southern Conference: "Are other animals on the farm, or humans, subject to infection by the same germ of abortion?"

Reply—Swine have been experimentally infected with the specific contagium of contagious abortion of cattle, but it is doubtful if a natural infection of them with it takes place to any extent. These animals do suffer from a contagious form of abortion, but the causal organism is a different strain to the one responsible for the disease in cattle. A number of cases have been recorded from different parts of the world of an indefinite and intermittent fever being set up in human beings through association with or handling cattle infected with contagious abortion, or through drinking raw infected milk, but it is not yet known just what are the factors necessary for the transmission of this trouble to man. However, as these cases so far recorded are comparatively rare and mild, and yet contagious abortion of cattle is extremely prevalent in all countries throughout the world, there appears to be no real occasion for alarm.

ORANGE SURVEY ON IRRIGATION AREAS.

REPORT ON AN INVESTIGATION INTO THE NATURE AND CONDITION OF WASHINGTON NAVAL ORANGE TREES GROWING IN VARIOUS ORANGE GROVES OF THE BERRI IRRIGATION AREA.

[By F. R. ARNDT, Horticultural Instructor of the Upper Murray Irrigation Areas.]

(Paper read at the 44th Congress of the Agricultural Bureau, September, 1933.)

In the year 1927 the Chief Horticultural Instructor (Mr. Geo. Quinn) initiated the idea of conducting an investigation into the nature and condition of Washington Navel orange trees as grown in the orange groves of the Murray Irrigation Areas and in collecting data in connection therewith, the main object of such research being to ascertain the type, productiveness, or other features of the individual trees, so that these could be classified into a number of grades according to their various characteristics. The chief outlines for conducting such a survey were submitted by Mr. Quinn to Mr. H. Beriman (Horticultural Instructor of the Mid-Murray Irrigation Areas) and to the writer, and in collaboration with each other a scheme was evolved for carrying out this work and for putting it into execution.

OBJECTS OF THE INVESTIGATION.

The main objects of the investigation were briefly as follows:—

Firstly.—To ascertain the nature or type of the individual trees, and to find out if these were of the true Washington navel type, or of the “off type” navel strain.

Secondly.—To discover the relative productiveness of the individual trees of the grove so that the profitable trees as well as the unprofitable ones could be indicated.

Thirdly.—To endeavor to discover the reason for variations in the health and productiveness of individual trees, and to ascertain if these differences were due to hereditary or environmental factors.

Fourthly.—To take note of trees of high productivity producing fruit of first-class quality, the bud wood of which would be suitable to use for propagating purposes.

METHODS OF INVESTIGATION.

Seven typical orange groves were selected for the carrying out of the investigation the individual trees of which were annually examined during the months of May & June before much harvesting of fruit had taken place, and their records were taken during the six consecutive years of 1927 to 1932, inclusive. The data collected in connection with the survey was entered on the spot into field books in which the position and number of the tree rows, as well as those of the individual trees, were kept. The subjects upon which information was taken were as follows:—

1. *Habit of Trees.*—Whether high, spreading, or symmetrical.
2. *Condition of Growth.*—Whether vigorous, moderate, stunted, or yellow.
3. *Cause of Condition of Growth.*—Whether due to various soil conditions, such as seepage, salt, &c., or other causes.
4. *Quality of Fruit.*—Whether good, inferior, &c.
5. *Size of Fruit.*—Whether large, medium, or small.
6. *Approximate crop* of tree in bushel cases.

NUMBER OF TREES EXAMINED.

The number of Washington Navel orange trees that in this investigation I had under observation and of which I took records was somewhat over 5,000, and were situated on Blocks 1, 5, 7, 8, 9, 17, and 97 of the Berri Irrigation Area.

ESTIMATING THE CROPS.

The most important, as well as the most difficult, part of the orange survey was in trying to ascertain the quantity of fruit produced by the individual trees, as this was the chief means of discovering their commercial value. To obtain exact figures in regard to this matter it would, of course, have been necessary to weigh the fruit from each tree separately, but as there were over 5,000 trees to examine, and the time that could be spared for this work was narrowed down to five or six weeks each season, it was quite beyond the means of a single investigator to do this.

The method that was adopted was to carefully go around each tree and to make an estimate of what it was thought that the crop as measured in packed bushel cases was likely to be. Of course, such an estimate could be approximate only, as a considerable proportion of the fruit was often partly or wholly obscured by foliage or by other fruit which, coupled with variations in the size of the individual fruits, at times made calculations difficult and militated against the accuracy of the observations. However, as the estimates of the various trees were all conducted along the same lines the standard thus set up was thereby kept fairly constant, so that the calculations made, although only approximate, gave a fairly correct indication of the relative production of the trees.

Crop estimates made at the beginning of the season were at times checked with the grower's figures of the total amount of fruit harvested, which at times showed a considerable degree of accuracy. Thus, in the year 1931, the total orange crop of Block 17 was estimated to be 1,947 bushel cases, and later in the season the proprietor of this orange grove informed me that the total crop from his trees for the season had been 2,047 packed bushel cases, while in 1932 the estimated crop of this block was 1,751 cases and the actual crop 1,657 packed bushel cases.

THE "OFF-TYPE" NAVEL.

The investigation revealed the existence of a considerable number of trees in most of the orangeries of an inferior strain, usually known as the "off-type" navel. Compared with those of the true Washington Navel variety trees of this type are usually more upright in growth and sparser in foliage, while their fruit generally has a rougher and thicker skin, and is more acid in flavor.

The proportion of trees of this type to the total number of trees in the grove varied considerably in the various orangeries. Thus, on Block 8, out of a total of 503 navel trees no trees of the "off-type" strain were found, while on Block 1 they numbered 193 out of 635 navel trees, and on Block 17, 145 out of 336 navel trees. The total number of "off-type" trees discovered was 713 out of a total of 5,131 navel trees, or about 13.89 per cent. of the whole.

ORIGIN OF THE "OFF-TYPE" NAVEL.

In regard to the origin of the "off-type" navel there are two main theories in the field—one of which holds that it is a separate variety, and the other that it is due to "sporting" buds of Washington Navel trees "throwing back" to a more primitive strain.

On one plantation most of the "off-type" trees were found to be situated in a section by themselves separated from those of the true type. In this case the two classes of trees had apparently been budded in quantity from parent trees of two distinct types, probably by different nurserymen, and had been but little mixed when planted out in the orchard.

In another instance where the great majority of the trees were of the true Washington Navel strain several "off-type" trees were found amongst them, although all of the trees had come from the same nursery, which fact could perhaps be explained by the theory that the trees of inferior strain were "throw backs" from "sporting" buds accidentally taken from trees of the Washington navel variety.

That such variation at times occur was found to be the case in the orangery just mentioned (Block 5), in which a limb of an otherwise perfectly normal good type Washington Navel tree was discovered to be carrying a crop of very inferior "off-type" fruit, although the fruit on the other portions of the tree was of first-class quality. Had bud wood from this tree been used for propagating purposes during the spring or early summer months before the fruit had developed sufficiently to show its character, it is easily seen, as the two classes of growth differed but little from each other in appearance, how a considerable number of trees of the "off-type" strain could have been propagated in this way together with a greater number of trees of normal type.

VARIATIONS IN THE "OFF-TYPE" NAVEL.

Quality of Fruit.—The fruit of the "off-type" navel often varies considerably in character on different trees. As previously mentioned, the fruit is generally coarse and thick in the skin, and the juice is rather acid to the taste. There is, however, often a considerable difference in the size of the fruit of different trees, as well as in the thickness of their skins, but how much of these variations are due to the influence of either heredity or environment is difficult to tell, but probably both of these factors are at work. The fruit generally hangs fairly well on the trees, and is usually marketed when the Washington Navel Crop has been harvested, by which time it has usually increased considerably in sweetness.

Hardiness.—The "off-type" navel is not a hardy tree. During the investigation it was noticed in practically every instance that where the soil was affected by either salt or seepage the "off-type" trees showed the ill effects of these conditions much more quickly, and often sickened and died before adjacent trees of the true Washington Navel strain become adversely affected from such causes.

Productiveness.—"Off-type" trees are usually not nearly as productive in the matter of fruiting as are those of the true Washington Navel strain, and in many instances are very shy bearing, producing but a few dozen fruits per tree. The practice of cincturing the stems of these trees by means of a single cut made with a sharp knife in the spring when the flowers are falling has, where employed, generally increased their productiveness considerably, in many cases so much so as to make trees that previously were comparatively unproductive quite profitable after this method had been applied. Cincturing also often has the effect, on account of the greater amount of fruit thus produced, of absorbing much of the surplus vigor of the trees, in making the individual fruits much smoother and thinner in the skin, and thereby giving them a better appearance.

COMPARATIVE PRODUCTIVITY OF "OFF-TYPE" AND TRUE-TYPE NAVEL TREES.

With the exception of the trees of two orange groves, those of Blocks 1 and 17, time has not permitted a complete analysis being made in regard to the comparative productivity of all the "off-type" trees compared with all of those of the true Washington Navel strain of which records were taken during this investigation.

For the six years covered by the investigation the 193 "off-type" trees of Block 1 produced an estimated average of 2.03 bushel cases per tree per year, while the 442 true Washington Navel trees on this holding produced an estimated average of 3.16 bushel cases per tree per year, this being an increase of over 50 per cent. in favor of the latter variety.

On Block 17, which orchard has the largest grown "off-type" trees in the district, the difference in the production of the two classes of trees was not very great, the estimated average being 3.45 bushel cases per tree per year for the 145 "off-type" trees on the plantation and 4 bushel cases per tree per year for the 191 Washington Navel trees. On each of these orangeries both classes of trees were cinctured annually.

THE THOMPSON'S IMPROVED NAVEL.

A number of trees of the Thompson's Improved Navel variety were found in several orangeries. These trees were generally found to be good croppers, and appeared to be rather better bearers than those of the Washington Navel variety, although no data was collected in regard to this matter. In appearance the fruit of this variety when of normal type is generally fairly large, rather oval in shape, with a fine, smooth skin. The fruit ripens early—often at the end of May or early in June—but in quality is below that of the Washington Navel, and is often lacking in juice content and in flavor. In addition, the fruit at times is very variable, often differing in shape, appearance of skin, and in juice content on the same as well as on different trees.

THE WASHINGTON NAVEL.

This variety was found to be the best of the various strains of the navel orange met with during the investigation. The fruit of this variety also at times varied in size, shape, and flavor, but most of such variations could in the great majority of cases be traced to the influence of environment, of which the nature and condition of the soil appeared to be the most important. Other factors that also influenced the quality of the fruit were cultural operations and such climatic conditions as frost, heat, wind, &c.

No well-defined difference in the character of the individual trees of this variety and in the quality of their fruit that could readily be ascribed as being due to hereditary factors alone were met with, although it is probable that a number of slight natural variations existed that were not readily discernible and so escaped notice. Indeed, it was rather surprising to observe how small were the variations in the quality of the individual fruits where the trees were growing under good conditions, and among thousands of trees it was impossible to discover any that showed marked superiority over the others in regard to quality of fruit that could not be explained as being due to the influence of environment. The true Washington Navel appears to be a well-defined, staple variety with well-marked hereditary characteristics, being by nature less variable in character than either the Thompson's Improved or "off-type" navel strains, and only very occasionally gives rise to any definite bud mutations, as in the case of the limb of the tree previously mentioned.

ENVIRONMENTAL FACTORS GOVERNING CONDITION OF TREES.

The chief environmental factors that appeared to govern the condition of the trees, as observed during the period the investigation was in progress, were as follows:—

1. *Nature of Soil.*—The nature of the soil of the orangeries under observation was in most instances a fairly deep sandy loam which, however, varied in places, both in texture and in depth. The trees generally grew well where the land was fairly loose and of a depth of 2ft. to 3ft. or more before a subsoil of loose calcareous marl was reached.

2. *Injury to Trees Due to Washing of Soil.*—On several orangeries a number of trees were found to be injured where there were steep irrigation runs on account of a considerable portion of the surface soil having been washed away. This had left the trees standing on mounds with very little surface soil around their main roots, with the result that the trees had become stunted in growth.

SUPPLIES OBTAINABLE FROM ALL DISTRIBUTORS.

Culture.—On the various orange groves under review the trees had been well cared for in regard to routine tillage operations, and the growers concerned were alive to the fact that orange trees required liberal supplies of nitrogenous fertilisers annually, which were generally applied either in the form of sulphate of ammonia, blood manure, or nitrate of soda, the rate of application varying with the different growers, but probably being on an average equivalent to about 5cwts. of sulphate of ammonia per acre.

Injury to Trees Due to Salt or Seepage.—Observation revealed the fact that where the trees were not thriving—with the exception of a comparatively small number growing on naturally unsuitable soil—that the cause of their inferior condition was also invariably due to adverse soil conditions brought about by salt or seepage troubles, or by the washing of the soil away from their roots on steep irrigation runs.

To cope with the seepage and alkali menace lines of underground tile drains had been put down in most of the seepage areas by the growers concerned with the object of removing the surplus underground water so that the water-table of the affected land would thereby be lowered. Where the drains had been put down before these adverse soil conditions had developed sufficiently to do much damage the trouble was usually checked or overcome, but where drainage operations were delayed until the soil had become bodily affected the injury done to the trees was often so great that these obtained but little relief therefrom—and at times even died—after the land had been drained.

CLASSIFICATION OF TREES.

To determine the relative value of the individual trees these were classified into five different grades according to their health and vigor, habit, quality of fruit, and estimated crop production during the six consecutive years that they were under observation. The following is a description of the various grades:—

Grade No. 1 was represented by vigorous growing trees of good habit that had produced good quality fruit of an estimated average of two or more bushel cases per tree per year.

Grade No. 2 was represented by moderate to vigorous growing trees of good habit that had produced fruit of good quality of an estimated average of one or two bushel cases per tree per year.

Grade No. 3 was represented by “off-type” navel trees of moderate to vigorous growth that had produced fruit of an inferior quality of an estimated average of one or more bushel cases per tree per year.

Grade No. 4 was represented by weak to moderate growing trees that had produced fruit of good quality of an estimated average of less than one bushel case per tree per year.

Grade No. 5 was represented by “off-type” navel trees of weak to moderate growth that had produced fruit of an inferior quality of an estimated average of less than one case per tree per year.

TREE CLASSIFICATION CHARTS.

For the purpose of readily showing the position and relative grades of the trees in the plantations, tree classification charts were made of the various orangeries with the grades of the individual trees marked in numbers.

In making the plans these were, with one exception where dots were used instead, divided into small sections, each section having the form of either a square or a rhombus, according to the angles that the trees were situated to each other in the orchard, and each of these spaces was used to represent one orange tree. Numbers ranging from 1 to 5 were then placed in the centre of the squares or spaces to indicate the grade of the trees.

Trees of Grades Nos. 1 and 2, representing the most profitable trees, were indicated on the plan by the numbers 1 and 2 placed in the centre of the squares and marked in blue.

Trees of Grades Nos. 3 and 5, representing the "off-type" navel strain were indicated on the plan by the numbers 3 and 5 placed in the centre of the squares and marked in red.

Trees of Grade No. 4, representing trees of the Washington Navel type that were lacking in vigor and productiveness were indicated on the plan by the number 4 placed in the centre of the squares and marked in yellow.

GROUPING OF GRADES.

The most noticeable feature revealed by the examination of these plans was the fact that the trees were generally found to be grouped together according to their grades, and as the numbers used to indicate the grades were marked in different colors this relationship was often apparent at a glance.

With the best type of trees—those classed as No. 1—these were generally found to be situated in groups by themselves, although at times No. 2 trees were found to be in close proximity to them. Again, No. 4 trees were generally found grouped together, often with No. 2 trees near them, but only seldom having No. 1 trees in their vicinity. This relationship of the trees of these three grades, which were all of the true Washington Navel type, was in most instances due to variations in the nature and condition of the soil, as the investigation revealed the fact that the No. 1 trees were generally found growing where the best soil conditions existed, the No. 2 trees where the soil conditions were of a somewhat less favorable nature, and the No. 4 trees where the soil conditions were adverse, such as on land affected with salt or seepage.

It was therefore apparent that the differences in health, vigor, and productiveness of the trees represented by Grades Nos. 1, 2, and 4 could in the great majority of cases be ascribed to the influence of environmental factors, and only slightly if at all to variations in type.

The "off-type" trees, represented by Grades Nos. 3 and 5, were also in several instances found to be grouped together, but as previously stated in such cases these had probably been budded in quantity in the nursery and had been planted together when being set out in the orchard. In other cases again, trees of this type were found scattered among those of the true type.

Although the investigation revealed the fact that the "off-type" trees in certain directions were often highly sensitive to the influence of environment, as under adverse soil conditions a No. 3 tree would often degenerate into one of the No. 5 type, yet under good conditions of soil and culture these trees, although often becoming more productive, seldom showed much improvement in their habit of growth and in the quality of their fruit, which remained distinctly "off-type," showing that these characteristics were due to hereditary and not to environmental factors.

TREES OF HIGH PRODUCTIVITY.

As mentioned at the beginning of this paper, one of the chief objects of the investigation was to ascertain if any trees of outstanding merit in the matter of productiveness combined with high quality of fruit existed in any of the orchards.

In regard to the quality of the fruit from trees of the true Washington Navel strain the remark has already been made that such natural variations as were found to exist were only slight. The chief differences were mostly confined to the size of the fruit, thickness of rind, and flavor of juice, and although in some

instances these properties may to some slight extent have been due to variations in the type, in the great majority of cases it was plainly apparent that they were due to environmental factors, such as the nature and condition of the soil and to methods of irrigation, fertilisation, and cultivation.

In the quest for trees of high productivity it was rather surprising to find that after examining thousands of trees of the true Washington Navel type that only a few showed any marked superiority in this direction over the others. The fact that the good bearing trees—those classed as Grade No. 1—were in practically all instances found to be growing in first-class citrus soil, and had, moreover, received good attention in the matter of watering, manuring, and cultivation, clearly indicated that here also environment was again the chief controlling factor.

Trees that had produced an estimated average of six cases per tree per year for the six-year period covered by the investigation were found in all of the orangeries. Those having averaged seven cases per tree per year were much less common, while only three trees—situated on Block 5—were credited with having averaged eight cases per tree per year.

These figures may not indicate a very high average yield for the very best trees, but to obtain a true perspective of individual tree production the distance that the trees are situated from each other in the orchard must be taken into consideration. The great majority of the trees were situated 20ft. apart from each other—including the three most productive trees—and thus numbered about 100 to the acre, and it is reasonable to suppose that had they been planted further apart that on account of their roots having more ground to feed in their individual yields would have been greater.

These highly-productive trees would, of course, make good parent trees for propagating purposes if only for the quality of their fruit, but as the beneficial influence of good environmental conditions was plainly apparent with them all, it was impossible to discover how much of their productiveness was due to hereditary factors that could be transmitted through their buds when worked on to the stocks of other citrus trees.

VALUE OF AN ORCHARD SURVEY.

The chief practical value of an orchard survey by means of a thorough examination of the individual trees lies in the fact that by this means it is possible to assign a definite value for each tree in the orchard, which may serve as a guide when attempts at improvement or reconstruction are made.

The easiest way to effect such an improvement would be to raise the grades, wherever possible, from a lower to a higher level. Thus, in the orange survey under review, the trees of Grades Nos. 1, 2, and 4, which were all of good type but owed their condition to differences in their environment, attempts at improvement would consist of the laying down of a better drainage system, or in using improved methods of irrigation, cultivation, or manuring, as the case might be, so as to raise the trees of No. 4 Grade to those of No. 2 Grade, and the trees of No. 2 Grade to those of No. 1 Grade. In regard to the "off-type" trees—those represented by Grades Nos. 3 and 5—these could be worked over to trees of good type so as to produce a better class of fruit.

If made use of in this way an orchard plan is of considerable value to the orchardist in enabling him to increase both the quality and quantity of the fruit from his trees, and thus be an aid to him in his efforts to make his plantation a more profitable one.

CARE OF MILK AND CREAM ON THE FARM.

[By W. N. RULE, Butter Grader and Factory Inspector.]

(Paper read at the 44th Congress of the Agricultural Bureau, September, 1933.)

The quality of nearly every crop on the farm is to some extent influenced by the climatic conditions of each season, over which the farmer has no control.

When it comes to the quality of dairy products, however, the weather is not a ruling factor, because the sweetness, and to a large extent the flavor, of milk or cream are not entirely dependent on climatic conditions, but are under the control of the farmer.

The farmer, if he chooses to do so, can easily protect milk and cream from climatic or weather influences throughout the year. Everyone who understands farm conditions will undoubtedly agree that quality in the milk and cream sold from the farm has at least this one advantage over the quality in other products and crops sold from the farm. The responsibility of the milk producer is the first point to be considered in our efforts to improve the quality of all dairy products. If we start with that statement as an accepted fact, the next question is: Why is so much inferior milk and cream produced on the farm?

IMPROVEMENT OF FARM DAIRY PRODUCE.

To give some idea of the average quality of milk and cream sent to cheese and butter factories, a review of the export gradings of cheese and butter will help you to realise that there is a great need for improvement in the quality of milk and cream that is produced in this State. If the market overseas is to be held against our competitors, then it is essential that the quality of local produce be kept up to that of other exporting countries.

The following are the export gradings of cheese for the season July 1st, 1932, to June 30th, 1933:—

Choice grade	626 crates = 5.12 per cent.
First grade	11,024 crates = 90.17 per cent.
Second grade	575 crates = 4.70 per cent.
Total crates	12,225 = 1,510,000lbs. approximately

The small percentage of cheese grading choice indicates that there is something wrong with the supply of milk to the cheese factories, and the general faults in the quality of the cheese commented on by the grader point largely to defects in the quality of the milk supplied by farmers.

To produce butter and cheese of good flavor and keeping-quality, strict attention must be paid to the treatment of milk from the moment it is drawn from the cow.

CARE OF DAIRY UTENSILS.

Most of the defects in dairy produce are due to dirty methods in the milking shed and neglect of cooling the milk or cream. Some people have the idea that a strainer will remove any dirt which enters the milk. This is quite wrong, because much of the dirt is dissolved, and the finest strainer cannot catch the bacteria which are responsible for most of the defects in butter and cheese. The only satisfactory method is to prevent dirt from entering the milk. This can be done by taking proper care of the dairy utensils.

Every dairy should be supplied with proper conveniences for cleaning the various utensils. Brushes are much better than cloths. They remove dirt from the corners, and can themselves be kept clean more easily than cloths.

Nothing provides a better breeding place for germs than a dirty cloth. Cans should be washed in tepid water before they are scalded, this is because hot water causes the albumen to coagulate and form a scum, which is difficult to remove. After washing in tepid water, scrub the cans in hot water containing soda; then scald in clean boiling water; if possible dip them into a large open copper. Place the cans and utensils in the oven to dry.

They should not be dried with a cloth, the water will be evaporated quickly by the heat of the metal, if they have been properly scalded. This method of cleaning keeps tinware bright, free from germs and rust, and does not injure the coating of tin. It is also important that the cows should be kept clean; do not drive them through mud if it can be avoided. Many cow-yards are allowed to get very dirty indeed, and in wet weather are covered with liquid filth, this sticks to the cows, dries, and probably falls into the milk. The yard should be covered with concrete and should slope slightly towards a drain at one side; it can then be easily cleaned.

The cow's udder should always be washed before milking, otherwise small pieces of dried mud are almost certain to fall into the milk pail.

Two other points to remember are to throw away the fore-milk and to strip clean. The fore-milk consists of the first two or three squeezes of milk from each teat.

This milk is liable to contamination by germs entering through the teat, and as it usually contains only 1 per cent. of butterfat little is lost by always rejecting the fore-milk. Thorough stripping is important for several reasons:—

1. The "strippings" are the part of the milk richest in butterfat.
2. Clean stripping develops the udder.
3. It helps to keep up the milk yield.

MILKING.

Before commencing to milk, the milkers should always wash their hands; they should not wear the oldest and dirtiest clothes obtainable, but clean overalls, which should be kept especially for the purpose and regularly washed.

Sometimes when there is difficulty in milking through soreness of the cow's teats, a little vaseline may be rubbed over the teats after they have been washed. Milkers should never use fore-milk for moistening the teats; moistening the hands with milk at any time is a filthy practice. Remove the milk immediately from the milking shed where it is liable to be contaminated by bad odors and particles of dirt.

As soon as it leaves the milking shed the milk should be strained. This is done by pouring it through a fine metal strainer which removes any solid particles of dirt. Bacteria and dissolved dirt, however, the strainer cannot catch; a fine cloth strainer should be used to remove the very minute particles; it must always be sterilised by boiling before it is used, because a dirty strainer is worse than none at all. Having strained the milk, the next thing to do is to aerate and cool it to as low a temperature as possible.

Aerating is very beneficial, if it is done in a clean atmosphere away from smells and dust. It allows the food flavor to escape, and by quickly cooling, the growth of germs is retarded. Generally the aerating is done during cooling, and as the milk runs over the surface of the cooler it receives a thorough airing.

Aerating in a hot or impure atmosphere does nothing but harm.

When the milk is drawn from the cow it is at an ideal temperature for the growth of bacteria; it should therefore be cooled immediately if intended for sale. If it is to be used for butter making it is separated while warm, and the cream should be cooled at once.

It is remarkable how very few farmers cool their milk or cream. Cooling can be done by placing the cans of milk or cream in cold water, but better results can be obtained by using a cooler. There are various types on the market, and they are to be obtained at very reasonable prices.

MILKING MACHINES.

I am of the opinion that a great many defects in milk and cream are caused by milking machines that are not kept in a clean condition. Unless machines are kept clean the milk will be of inferior quality to that obtained by hand-milking, and I advise the following method to clean them:—

Before commencing milking, cold water should be drawn through the pipes to prevent milk from adhering to them. The solids become very adhesive if allowed to dry; cleaning must therefore be regular, and immediate and special attention paid to the following:—

1. Wash dirt from outside of teat-cups.
2. Draw through cups and releaser plenty of tepid water, then boiling water and caustic soda (1½ tablespoons of caustic soda to 4galls. of water), and finally pure boiling water.
3. Clean the releaser-pipe by drawing through it a ball of horsehair at the same time as the water from the farthest set of cups.
4. Remove teat-cups and rubber parts and protect them from dust.
5. Wash vacuum pipes and tank, leave parts open to air.
6. Disconnect and wash releaser.

Each week immerse all rubber parts in cold water with a little soda added, and heat to boiling point, then place them in pure cold water. If these instructions are carried out when washing milking machines there will be no trouble with defects in milk and cream that arise from careless cleaning of machines.

The cheesemaker cannot make good cheese unless he has good, clean, raw material to start with, therefore, the responsibility lies with the producer to see that milk is produced under the best conditions possible, so that the milk will not contain bacterial infection from such causes as unclean condition of the cows, bails, milker and dairy utensils, especially milk buckets, strainers, milk cans, and parts of the milking machines.

Milk, particularly when warm, possesses remarkable ability to absorb and retain odors, present in the surrounding air, so that every care should be taken to keep the bails and dairy clean and sweet smelling. Another most important factor is the aeration and cooling of milk, this should be done immediately after milking, and must only be done where the air is clean and sweet smelling. Unless performed under proper conditions, aeration may be the means of contaminating the milk with undesirable bacteria.

Cleanliness and prompt cooling of the milk are two of the most important factors that enter into the successful manufacture of good cheese and butter.

QUALITY OF CREAM.

From personal experience I say definitely that the average quality of the cream received by the factories leaves very much to be desired.

The percentage of choice cream is very small indeed, the bulk of the cream received is just an ordinary first grade, and presents a very difficult task for the buttermaker to produce choice butter, and he has to rely on skilful grading and an

expensive plant to help him to get the results that he does. The following figures show the percentages of choice, first, and second grade butters that were graded for export for the season July 1st, 1932, to June 30th, 1933:—

Choice grade	50,770 boxes = 29.16 per cent.
First grade	101,331 boxes = 58.20 per cent.
Second grade	16,790 boxes = 9.63 per cent.
Pastry grade	5,214 boxes = 2.99 per cent.
Total number of boxes . .	181,105 = 9,749,880lbs.

When these grades are compared it will be realised that the production of choice grade is by no means as great as it should be, the reason for it is poor quality cream that is produced on farms. Most of the defects in cream can be traced back to the careless production of milk in the first instance, careless cleaning of the separator, neglecting to cool the cream, keeping it in an impure atmosphere, using petrol tins with open seams, and old, dented, and rusty cans.

I have seen cream in cans that had holes in them stopped up with soap and rag, cans that were dented and badly rusted, cans that have been painted inside and out with silver frost to try and hide their defects.

The fact that a can is rusty indicates that the tin coating has become defective in spots and that the iron is exposed. The exposed iron is acted upon by the acid and other constituents of the cream, causing the formation of metallic salts which hasten decomposition of the cream, either through chemical action or by accelerating the action of bacteria.

Such action may lead to diverse flavor defects in butter, such as metallic, tallowy, and fishy flavors. Rusty cans are objectionable also for sanitary reasons. Rust spots present a rough surface on which remnants of milk and cream lodge and from which they are difficult to remove.

Rusty cans also retain moisture in such a way that they are difficult to dry; they cannot be kept perfectly clean; they become foul-smelling and pollute the cream that is put into them.

All these points are controlling factors that determine the quality of the cream that reaches the factory. Contact of cream with anything that is unclean, be it the cow, the milker, the stable air, or the separator and utensils, is a detriment to quality.

The damage may result from absorption of objectionable flavors and odors or from contamination with undesirable bacteria. It is, therefore, of the greatest importance to produce cream with due regard to cleanliness and sanitation.

THE SEPARATOR.

One of the main sources of contamination is the separator, it is a collector of many impurities that are found in the slime which is deposited on the wall and internal contrivances of the bowl.

This slime consists of a large portion of the dust, dirt, and bacteria which may have reached the milk during its production.

It is most essential that strict attention be given to the cleaning and sterilising of this most important piece of machinery. It should be dismantled and washed immediately after each separation. The cream should always be cooled as soon as it comes from the separator and not stored in a musty or badly ventilated cellar.

Warm cream is in ideal condition for bacterial growth and decomposition. The only practical way to cool cream promptly and to successfully control the temperature under average farm conditions is to permit it to flow over a water-cooled surface cooler, or to set the cream cans in a properly insulated tank filled with cold water. The heat conductivity of water is 21 times as great as that of air. This means that by setting the cans in water, the cream will be cooled 21 times quicker than by letting them stand in the air at the same temperature.

COMMON DEFECTS IN CREAM.

Over-ripe Cream.—Caused by excessive acidity which develops when cream is not cooled off after separating. This may be prevented by separating the cream at a test not less than 45 per cent., then cool the cream immediately after separating, keep it in a cool place and deliver to the factory frequently.

Fermented Cream.—Caused by the growth of germs which produce gas in the cream. These germs come from cow manure and get into the milk during the process of milking. Fermented cream is an indication that the milk has been produced under dirty conditions. Manure should be removed promptly some distance from the cow shed. Pay strict attention to cleaning plant and premises; use boiling water for scalding utensils morning and evening. Wash the cow's udder clean, and milk with clean hands; cool the cream after separating.

Stale Cream.—Caused by holding the cream too long at the dairy, or putting a small amount of cream left over into the next can, and held over for the next delivery. This can be avoided by sending all the cream in the dairy to the factory. A little stale cream very quickly spoils a lot of good cream.

Rancid and Cheesey Cream.—Caused by infrequent delivery to the factory. It is due to over-staleness, uncleanness, and germ infection. This class of cream is liable to be condemned as unfit for making into butter. A thorough cleaning of buckets, separators, milking machines, &c., is recommended, and more frequent delivery to the factory.

Unclean Flavor in Cream.—This is caused by faulty cleaning of milking machines, separators, and other utensils; old, broken, and rusty utensils; using cloths for washing up. Unclean methods in the dairy generally; these may be prevented by thoroughly washing all dairy utensils and scalding them well with boiling water. This must be done immediately after each time they are used. Use clean, sound brushes instead of rags, and adopt cleanliness throughout. Do not mix hot and cold cream; wait until all is thoroughly cooled.

Feed Flavors.—These are brought about by the cows grazing on the rank growth of some weeds, clover, lucerne, and other feeds. If it is possible to do so, keep the cows from weed growths; feed clover, lucerne, &c., for a short interval after milking, and then remove to ordinary pastures. Cool and aerate the cream immediately after separating.

Curdy Cream.—This generally occurs when the cream is separated too thin—below 38 per cent. test—and not keeping too cool. Cream should be skimmed to contain not less than 42 per cent. butterfat, be cooled immediately after separating, stirred frequently with a clean, tinned metal stirrer, and kept cool.

Ropy Cream.—Caused by germ infection, which comes from swamps, dams, and low-lying paddocks, and is carried from there by the cows to the dairies and utensils. Cows should be prevented from wading in swamps and waterholes, and the udders washed thoroughly before milking. Whitewash dairy and bails, and scald utensils with boiling water to remove infection.

Tallowy Flavor in Cream.—This defect is due to sunlight shining on the cream, which sets up a chemical change—oxidisation—particularly is this so with very high testing cream, 50 per cent. and over; it may also be caused by undesirable germ infection. Keep the sunlight from the cream. Do not expose excessive surfaces of cream to the air for any length of time, and keep all utensils and surroundings clean.

Metallic Flavor.—This is the result of using rusty cans and dairy utensils, and may be caused by unclean tinware. Discard all rusty cans and dairy utensils. Rusty cans and buckets and dented cans are too expensive to use. Use only well-tinned seamless cans and buckets.

Absorbed Flavor.—Milk and cream quickly absorb flavors, and should not be left in a room where the exhaust fumes from the oil engine or odors of the engine are prevalent. It should be kept away from oil smells, such as oil on the floor or separator block, smoke from the fire, any strong-smelling materials, chemicals, and disinfectants. Cream should be kept in a room that has a clean, pure atmosphere. Do not wash dirty utensils with the hot water from the engine jacket.

Cowry Flavor.—This is caused by unclean condition of the bails, floors, yard, etc., not washing the udder of the cow, milking with dirty hands, milking unhealthy cows, or using the milk too soon after calving. The udders and teats should be washed, and milking done with clean hands. Bails should have concrete floors, and the yards be kept clean. Never separate milk from sick cows that have just calved.

Choice grade cream must score 42 points or over, and must be sweet and perfectly clean in aroma and flavor.

First grade cream must score at least 39 per cent. = 41 points, and must only be slightly affected by feed flavors, absorbed odors, or taints. It may be high in acid, but must be free from staleness.

Second grade cream must score at least 36 per cent. = 39 points out of 50 for flavor, and is a cream with strong feed or weedy flavors, unclean taints and flavors, absorbed flavors, and metallic, and produced amidst unclean surroundings.

Third grade or pastry cream is a cream scoring 35 points or lower for flavor, and consists of badly fermented cream, dirty, strong metallic, stale cheesy, and very pungent weed flavors, such as wild turnip, garlic, &c. Anything below this standard should be rejected as unfit for human consumption.

Do Not Let Prices Mislead You

EXPERIMENTAL ORCHARD, BERRI—EXPERIMENTS ON THE STEAMING OF FIGS.

[N. S. FOTHERINGHAM, R.D.A., Manager Berri Experimental Orchard.]

(Paper read at the 44th Congress of the Agricultural Bureau, September, 1933.)

The figs harvested at this orchard during 1931 and packed from June onwards showed, when opened up in Melbourne, much mould. The mouldy figs in question, so far as we know, were the ones held in store for some considerable time. As this was the first occasion on which reports of this nature had been received, we were naturally anxious about the position; not only this perturbed us, but in addition the various fig growers, including ourselves, having decided to hand over the packing and marketing of the figs to the Berri Co-operative Packing Union, who, with certain modifications for convenience, were to pack on lines of procedure more or less formulated at his orchard. We, therefore, deemed it necessary to carry out tests to try to determine the cause of this mould growth. As the figs that went mouldy showed much moisture when opened, it was naturally thought that the steaming and packing had something to do with this.

Figs can be harvested:—

- (a) Either by picking when they reach a wilted condition.
- (b) The boughs may be shaken and figs gathered from the ground.

With (a) the figs are definitely of a fresh nature and have a green or yellowish-green appearance. We term these figs for descriptive purposes "green."

With (b) the figs shaken from the tree are mostly well wilted and partly dried and have a certain proportion of "green" figs in them, which are picked out and treated separately. The bulk of the (b) method of harvesting are termed for descriptive purposes "partly dried."

The general method employed in packing the dried figs is to pack and press them steaming hot into 1lb. cellophane wrapped and labelled packs and to pack these in turn into boxes holding 36lbs. of packed figs, consisting of six layers each containing six packets of figs.

As previously mentioned, it was considered possible that the process of steaming and packing had something to do with the after development of mould, and as figs classed as "green" and "partly dried" were both used in our commercial packs in which mould had occurred, it was considered necessary to consider this phase in any experiments to be carried out. Experiments were therefore designed to test:—

- (a) Time of steaming on—
 - (1) Partly dried, and
 - (2) Green figs.
- (b) Packing into separate boxes packets of "partly dried" and of "green" figs hot from the steam bath.

Packing into separate boxes "partly dried" and "green" figs after being allowed to cool.

The times of steaming tried out were 8, 10, 12, 15, and 20 minutes. It was set out that "partly dried" and "green" figs should be steamed for these various times and that one box of each would be packed into boxes when hot and another after they had been allowed to cool. Unfortunately there were insufficient "green" figs to carry this out in its entirety.

The undermentioned shows the tests carried out:—

Time of Steaming.	"Green" Figs Packed into Boxes when Cool.	"Green" Figs Packed into Boxes when Hot.	"Partly Dried" Figs Packed into Boxes when Hot.	"Partly Dried" Figs Packed into Boxes when Cool.
8 minutes	Packed 13.5.32	Packed 11.5.32	Packed 27.4.32	Packed 28.4.32
10 minutes	—	—	Packed 13.5.32	Packed 13.5.32
12 minutes	Packed 16.5.32	Packed 13.5.32	Packed 12.5.32	Packed 12.5.32
15 minutes	Packed 11.5.32	Packed 11.5.32	Packed 12.5.32	Packed 12.5.32
20 minutes	Packed 2.5.32	Packed 6.5.32	Packed 2.5.32	Packed 6.5.32

The figs were packed from April 27th, 1932, to May 16th, 1932, and were opened and inspected by Mr. F. McGlasson (manager of Berri Co-operative Packing Shed) and myself on December 3rd, 1932. They had, therefore, been packed and stacked in a block for well over six months and much in excess of the period of holding the figs of the previous year that moulded.

A description of each of the packs opened up is as follows:—

STEAMED 8 MINUTES.

(1) *Green figs* packed into boxes when *cool*.—Fruit soft and pliable, packets free but sweating freely, very little white efflorescence showing on cellophanes. Labels stained badly. No mould.

(2) *Green figs* packed into boxes when *hot*.—Fruit soft and pliable, packets free but sweating freely, very little white efflorescence showing on cellophane. Labels stained badly. No mould.

(3) *Partly dried figs* packed into boxes when *hot*.—Fruit pliable but not as plastic as green figs, packets free, very little white powder present. Labels not stained too badly, and packets not sweating nearly as much as those containing green figs. No mould.

(4) *Partly dried figs* packed into boxes when *cold*.—Condition about the same for pliability as those packed hot. Packets free. Very little white efflorescence, practically no stain on labels. No mould.

STEAMED 10 MINUTES.

(1) *Partly dried figs* packed into boxes when *cool*.—Fruit pliable and free, not stained as much as 12 min. green cool test. Not much white "sugaring" on cellophane wrapper. No mould.

(2) *Partly dried figs* packed into boxes when *hot*.—Fruit soft and pliable, more so than previous test. Very little of the white powder showing on cellophane wrapper. Labels badly stained. No mould.

STEAMED 12 MINUTES.

(1) *Green figs* packed into boxes when *cool*.—Figs pliable, but packets stuck to one another. White efflorescence showing on cellophane wrappers and stain on the labels. No mould.

(2) *Green figs* packed into boxes when *hot*.—Nice and pliable fruit, sweating fairly freely. Packets sticking badly, very little white sugariness showing on cellophane wrappers, but labels badly stained. No mould.

(3) *Partly dried figs* packed into boxes when *cool*.—Pliable texture, packets free in case, but more white efflorescence showing on cellophane wrappers, labels not so stained as green figs. No mould.

(4) *Partly dried figs* packed into boxes when *hot*.—Nice and pliable fruit, packets not free in case, very little white powder on cellophane wrappers. Labels badly stained. No mould.

STEAMED 15 MINUTES.

(1) *Green figs* packed into boxes when *hot*.—Fruit nice and pliable and free, very little white "sugar" showing on cellophane wrappers, sweating freely. Labels very badly stained. No mould.

(2) *Green figs* packed into boxes when *cool*.—Nice and pliable in texture, packets free in case, packets very white and powdery on side. Labels badly stained. No mould.

(3) *Partly dried figs* packed into boxes when *hot*.—Figs nice and pliable, packets free in case. Labels stained fairly badly. No mould.

(4) *Partly dried figs* packed into boxes when *cool*.—Nice and pliable texture, fairly free in case. A little whiteness showing on cellophane wrappers. Labels stained fairly badly. No mould.

STEAMED 20 MINUTES.

(1) *Green figs* packed into boxes when *hot*.—Nice and pliable fruit, packets free in case, sweating freely, very little white sugariness on cellophane wrappers. Labels badly stained. No mould.

(2) *Green figs* packed into boxes when *cool*.—Fruit nice and pliable, packets free in case, sweating freely, very little white efflorescence on cellophane wrappers. Labels stained fairly badly. No mould.

(3) *Partly dried figs* packed into boxes when *cool*.—Nice and pliable condition, packets free in cases, not a great deal of stain, a little white powderiness on cellophane wrappers. No mould.

(4) *Partly dried figs* packed into boxes when *hot*.—Figs nice and pliable, packets free in cases, very little white powder on cellophane wrappers. Labels stained slightly. No mould.

It was noted in examining the boxes that the smell of the figs was good in all cases and there was no sign of sourness.

It was hoped that the experiments carried out would have given some indication of the mould cause, but as there was not a mouldy packet in the 18 boxes little information has been gained on that point.

The tests, however, have disclosed that the "green" fig sweats more freely than the "partly dried," even when steamed for eight minutes only. The "green" fig is also more pliable and softer to the touch than the "partly dried."

It is noted that practically in the whole of the figs under test that the staining of the labels increases with each lower layer of figs, although it is certainly worse under a longer steaming and with "green" figs. The effect of this staining of labels is that when figs have been kept for any length of time and are opened up the attractiveness of the product is spoilt. It may be possible to limit this staining considerably by using shallower boxes, packing the boxes so that each pound of figs does not press directly on the other beneath it, putting division papers between the layers, and stacking the fruit in well ventilated rooms so that air currents can get between the boxes.

In addition to the above, it may be wise to under-steam the figs rather than over-steam. The condition of the figs opened shows that figs with 10-12 minutes steaming are soft and pliable.

A REVIEW OF THE SOUTH AUSTRALIA VINTAGE, 1932-33.

[By J. L. WILLIAMS, R.D.A., Lecturer in Viticulture, Roseworthy College.]

The 1932-33 season can be regarded with very mixed feelings. The chaotic state of affairs which prevailed among wine-grape growers and the winemaking fraternity is still fresh in our minds. Although most winemakers have been cognizant of the imminence of such a catastrophe for the past 24 months, the average grapegrower little expected the blow to be as near or as severe.

The condition of the winemaking industry was, and still is, so serious as to have occasioned the recent visit to this State of a prominent Commonwealth Customs official.

A visit was recently made by State members to the Barossa district, this visit being organised by the Grapegrowers' Association. The members present expressed their sympathy with the grapegrowers, and departed feeling that the grower had just cause for feeling dissatisfied with his lot.

At the moment it appears that certain of the poorer types of vineyard soils in this State will go out of cultivation for vine growing, owing to the low yields and because of the prices received for the produce. It would appear that for the next few years it will only be produce possessing quality for winemaking purposes that will be in demand by makers of wine, and that the present position will only adjust itself according to the dictates of supply and demand. It is mainly red varieties—"Matara," "Grenache," and "Shiraz"—that are being over-

produced at the present time, and it would appear that growers of red wine varieties would be well advised to graft over portion of such vineyards to white varieties suitable for the manufacture of sweet white wine, for which there appears to be a good demand at the present time.

The season ending with the 1933 vintage opened very satisfactorily, good rains being received during the months of May to September, 1932, inclusive; the falls during these months varying from $\frac{1}{2}$ in. to 4 in. less than for the corresponding period of the 1931 season. In certain districts, however—*e.g.*, Barossa and the Southern wine districts—September was much drier than in the previous season, and growers who had left the ploughing of their vineyards until then found the soil rather dry for effective working. To obtain satisfactory vine growth it is imperative in most seasons to finish ploughing by the end of August, and to have the soil free from weeds and in good tilth prior to the commencement of warm weather towards the middle of September, otherwise an enormous loss of valuable soil moisture is the result.

The rainfall during the growing period was generally a trifle better throughout the non-irrigated districts than in the previous season. The Barossa district in particular received good rains in October (2.25 in.), this being fortunate in that it followed a comparatively dry September.

During early October, frosts were experienced in some districts and locations—in the Barossa district principally, subject to late spring frosts, suffered considerable damage. Later in the growing season a severe hailstorm passed over portions of this district, and practically removed or spoiled the whole of the crop on the vines, as well as damaging the fruiting wood for this season.

The rainfall received during the ripening period, January to April inclusive, was considerably lower (with the exception of the Barossa district) than during the same period of 1932. In all but the Barossa district better Beaumes were obtained than in 1932. Beaumes of more than 14 were difficult to obtain in this district.

Growers of dried vine fruits in the Clare and Watervale and Southern Districts, and River Murray Irrigation Settlements were favored with ideal drying weather, and in most cases the quality of the product was superior to that produced in the 1931-32 season. On the River the principal drying months, February, March, and April, were drier than usual; February being rainless, and during March and April only about $\frac{1}{2}$ in. was recorded. During the corresponding period of 1932, 3.24 in. of rain fell.

These favorable conditions were reflected in the quality of the dried product of the vines along the River; cold dipped fruits particularly were of a very high quality.

Despite the fact that a small portion of the grape harvest remained on the vines in certain localities, and that a large portion of the crop in the Barossa district was harvested very late, owing to the above-mentioned marketing difficulties, the State Government Statist, Mr. W. L. Johnston, estimates the production of wine for the 1932-33 vintage at 12,000,000 galls., an increase of 1,335,454 galls. (or $12\frac{1}{2}$ per cent.) over the 1931-32 vintage, based on figures obtained from vigneron's representing 96 per cent. of the previous season's total production.

Table IV. is taken from Mr. Johnston's forecast of the 1932-33 vintage, and is sufficiently explanatory.

In these tables Clare figures are taken to represent the Clare and Watervale districts; Tanunda, the Barossa district; Morphett Vale, the Southern wine districts; and Waikerie, the River Irrigation Settlements, respectively.

PAPERS READ AT CONFERENCES.

SOUTHERN BRANCHES, GOOLWA, AUGUST 17th.

THE FUTURE OF THE RIVER MURRAY.

[J. P. COLEBATCH, Port Elliot.]

In 1902 Senator Glynn, in an address on the "River Murray" before the Australian Natives Association, said that "Water transport is universally acknowledged to be the cheapest form of transport, the average per mile being about one-tenth that of land carriage." A glance at the map shows a vast area of land within a short distance of the Murray and its tributaries, and it is a well-known fact that where Nature has provided land, water, and a congenial climate, man by the application of industry, seed, and super, and the introduction of live stock, can provide all that is required for food, clothing, and shelter."

Not infrequently Australia is referred to as a "dry" country. The length of the Murray in South Australia is about 400 miles, and this, at an average width of 1,000ft., with a depth of 10ft., there would be no less than 22 thousand million gallons for every man, woman, and child in the whole of Australia, or a total of one hundred and thirty-two thousand million gallons. How much of this is used?

The locking of the river—so far as the South Australian border—is proceeding, and in a few years will be completed. Lake Victoria—an immense storage basin—is already filled. Work is in progress for the Hume Reservoir, which when completed is to hold more water than Sydney Harbor, and will be the second largest in the world. The cost of these works will be wasted unless the country adjoining the river is put to better use than at present and can support a much larger population.

Mr. Colebatch then visualized the Murray and its activities 200 years hence.

ESSENTIALS IN THE PERSONALITY OF THE FARMER.

[W. E. HARGREAVES, Port Elliot; read by H. L. SMITH.]

To-day no class of business man is receiving more attention than the farmer. Agriculture is now considered of sufficient importance to attract the attention of men of affairs, and while it is true that the farmer is slow and conservative, the average farmer is capable of great things, and agriculture is the most healthful, the most useful, and most noble employment of man.

The agricultural population of this State has been raised to the level of that of any other profession, and it feels the responsibility of the affairs of the State, for they rest as largely upon the farmer as any other class. In past history there was a sharp distinction between farmers and the "professions." Efforts were made to develop the brain worker mentally, and the farmer physically, believing that neither required development along the lines of the other. To-day people begin to understand that it requires brains as well as brawn to make a successful farmer. There is no business to-day that requires so much knowledge or closer attention to details. Indeed, a man on the land to be successful must be a man with brains. No man in any trade has so many irons in the fire at the same time; he must look after the fertilising and tilling of the soil, the proper time to sow, the right time to reap. He must study the best kind of stock best suited to his special locality, and a hundred and one other things.

[Papers Read at Conferences.]

All those require training of the reasoning faculties of the mind. There is an unwritten law that makes every vocation a part of every other vocation, each in turn must help or hinder others. To make and save money is honorable; it is a necessity, but this should not be the final object. Every effort should not be marked with £ s. d. signs.

At meetings of the Bureau subjects relating to dairying, sheep, pigs, horses and crops and their care and culture as having the most money value to the farmer are discussed. Is that the only object in trying to improve our conditions? We dwell so much on the commercial side of things that we forget there is another side to the question. It is interesting to see the care a farmer will take of a favored cow or horse. They must be kept clean and comfortable, have pure water to drink, and food must be of good quality and quantity. One cannot over-estimate the value of kindness to livestock. Experience goes to prove that kindness has a marked effect on the market value of the product. Thus the characteristics of the man will surely be reproduced in the stock he breeds.

The horses and cattle in their real worth to the Commonwealth are but a drop in the bucket as compared with the man who cares for them. Often there is more care given them, and they are better groomed, especially when they are on exhibition, than their master. The part of the farm most neglected is the farmer himself. "A diamond in the rough is a diamond sure enough," but that diamond is far more attractive after it has been polished. Why is there so little value placed upon the small things that make for the pleasant things of life? Are we not inclined to belittle ourselves and our occupation by so doing? The highest point of breeding is to show a very nice regard to your own dignity, to express your value to the man above you. More care should be given to our personal appearance, to dressing, speaking, &c. Manners may be considered small things, but if neglected are large enough to decide for or against

[Papers Read at Conferences.]

us. A little more attention given to the details of our personal appearance would prevent much criticism—criticism which you and I care nothing about, but which you and I have no moral right to entail upon our children whom we expect to keep on the farm.

Why should there be one code of manners necessary for the merchant, doctors, &c., and another for the farmer? Conservative as the producers are, we would lift our eyebrows in surprise to see them come to business with unshaven faces. Nor is there any reason why the farmer should go to town looking like a tramp. Such things are the result of habit.

There appears to be a wave of discontent among rural boys and girls; their ideals have been raised by education to a standard which their surroundings do not satisfy. What is the remedy—seeking to lower their ideals? By no means; elevate their home surroundings to meet their ideals. Let there be a constant incentive to make the very best of themselves. Parents have no moral right to damp the best side of the natures of those around them by always dwelling upon the profit and loss side of things. Do not commercialise every impulse. A happy, cheerful mind, and a well fed, well-groomed and well-clothed body are among the essentials in the personality of the man of the soil. It is not that more economy is wanted, but a better brand of it. The different departments of trade and professions are demanding specialists, and a majority of them have been, and continue to be, products of the farm.

THE MODERN CLYDESDALE.

[A. M. FULLER, Inman Valley.]

The Clydesdale is a breed of heavy draught horse indigenous to Scotland, and deriving its name from the district in which it was founded, and its type and characteristics were fixed and determined. Clydesdale is the old name for Lanarkshire, through which the River Clyde flows. The origin of the Clydesdale breed, according to Mr. William Aiton's writing in the year 1810, is the result of a cross between the native Scotch mares and some Flemish stallions imported into the country by one of the Dukes of Hamilton about the middle of the 17th century. These are said to have greatly improved the breed in the county of Lanark.

There are various strains of the Clydesdale breed which may be traced back through the medium of the Clydesdale Stud Book, such as those named in Lanark; the Gallo-way Clydesdales, the Kintore strain, the Old Stitcher line, the Banffshire Comets, and the old Clyde strain. In the west of Scotland the modern type owes much to the horse *Broomfield Champion* (95).

The outstanding characteristics of the Clydesdale horse are the combination of weight, size, and activity, with exceptional wearing qualities in respect to the feet and limbs. The head of a typical Clydesdale has a broad jaw, ending as a rule in a well-tapered muzzle with large, open nostrils; eyes full and vigorous, yet mild; forehead broad and full between the eyes; while from the eyes, the forehead tapers gradually up to the ears, which are long and active. Breeders of Clydesdales should attach much importance to these points, for a horse of such a description will generally be found to be of excellent temper, easily trained, docile, and very wise in harness.

Experience alone can teach one when the head is well set on the neck, but the latter should be strong, massive, and of medium height; while the shoulder should be more oblique than in the English draught horse. This, indeed, is one of the distinctive features of the Clydesdale, as is his long, quick step for which he is so justly admired. Quite as essential as the slightly oblique shoulder is a strong forearm. This part from a side view should be broad, loaded with long strong muscles to give full power to bring forward the part below, and in length should be proportionate to the length of the shoulder; a flat and broad knee is also essential. The shank bone should be flat from a side view, thick and gently rounded from a front view, and tapering to an edge as it goes back.

[Papers Read at Conferences.]

The back, from the knee down, should possess a nice flowing fringe of silken hair, which should spring from the very edge of the bone; good judges will not have a horse the feather of which has a coarse matted appearance. The sinews of the leg should be thick, strong, thrown well back from the bone, and capable of being felt by the hand; if not, the leg is not a good one, however thick, as a soft round leg in which the sinews are not very well defined will not stand work. The lower end of the shank bone or fetlock should also be large, to give full play to the tendons. Clydesdale judges are also very particular as to this; also to the pasterns. An upright pastern will not do in a Clydesdale, which requires a pastern to suit the formation of the shoulder, and to confer the necessary elasticity to counteract the concussion caused by his quick, firm step.

Without a sound, well-shaped, healthy foot a horse is of no use, however symmetrical and strong; the foot must be open and round to be healthy. The hoof heads must be wide and springy, with no suspicion of hardness, such as may lead to the formation of side bone or ring bone. The back should be short, ribs well sprung from the backbone like the hoops of a barrel, broad, low-set hindquarters, with muscular thighs, descending into broad and proportionally developed hocks.

To sum up the good points of the hind end of a Clydesdale, from the hock to the ground, the leg should be broad, short, flat, clean, even and straight, or slightly inclined forward. The sinews standing out from the bone, and having a similar fringe of hair to that of the foreleg and rising as high as the bottom of the hock joint.

The average height of a Clydesdale horse is about 16 hands 2 inches, though there are several stallions to be found as high as 17 hands, but very few over that height.

The fashionable color is brown: that of a deep, dark shade preferred, with more or less defined white mark on the face, while black is also common. White markings are now very common, and have come to be regarded as a sign of purity of blood. Greys are not very favored, being simply disliked, and Clydesdale breeders are decidedly adverse to chestnuts.

In examining a Clydesdale when standing, a good judge, in addition to running his eyes over the various points mentioned, will see that the animal stands even and firm on his feet, which in some horses are inclined slightly inwards; to be the least inclined outward is a bad fault, and one which gets worse with age. In walking, the horse should, if approaching you, come with his head well carried, and with an apparently measured stride, lifting his feet well off the ground and placing them down again regularly, evenly, and with apparent deliberation. On a side view one can notice if his action be even, if his fore and hind action be in unison, for in a horse with long back and weak loins the two ends seem to be under different control, and the hind legs being in a manner dragged with the toes along the ground an unpleasant effect is produced.

FRIENDLY SERVICE ALL THE TIME.

Some of the time, if not all the time, you must save money, but if you are Mr. Average Citizen you know that ALL the time is nearer the mark.

Whatever your margin on any one week's salary, it won't provide for a sudden necessity to pay, say, £50 or £100. No one week's salary will provide education for your children, heavy medical expenses, or comfort in your declining years.

Therefore, to make provision for the big calls, you HAVE to save, more or less, ALL the time. The Commonwealth Savings Bank provides a friendly efficient savings service ALL the time.

Commonwealth Savings Bank of Australia

GUARANTEED BY THE COMMONWEALTH GOVERNMENT.

[Papers Read at Conferences.]

In going away at a walk, a horse should plant his hind feet forward as deliberately as his fore ones, at the same time raising and bending the leg at the hock, which should be evenly carried forward. If the hocks are turned out when moving them forward, the action is not good, and a Clydesdale breeder considers this an exceedingly bad fault in either horse or mare. In trotting, the horse should bend his legs at the knees and hocks, and from a hind view the inside of the fore hoofs should almost be seen at every step.

If the animal be inclined to move wide behind, this fault will be easily discovered at the trotting pace.

PIG BREEDING AND MANAGEMENT.

[M. B. CASELEY, Milang.]

It is only within the last half-century or so that any particular care has been devoted to pig breeding. In England in 1884 there was formed "The National Pig Breeders' Association," and prior to that date there were no herd books, and few breeds—in the modern sense—can be said to have existed. In the case of the Berkshire—so frequently mentioned by old writers—it is clear that the old type was rather variable, and was in the main unlike the type of to-day.

During the past 30 years a few breeds have become extinct, whilst during the same period the number of recognised breeds has steadily increased. Thus the Large Black Breed Society dates only from 1899, the Gloucester Old Spots 1914, Wessex Saddleback 1918, and the National Long White Lop-eared 1922, to mention but a few. It is questionable whether this tendency to multiply breeds has not gone too far, for it is difficult to see that more than half-a-dozen breeds are necessary to meet all the requirements of the farmer, as well as those of the consumers. In fact, in the final analysis, from a business point of view, the wants of the consumer should be studied more than the fancy of the farmer.

The type of animal marketed depends not entirely on the breed, but largely on the system of rearing and feeding that is adopted in particular cases. Broadly speaking, however, the bacon-curer desires an animal which will dress at 120lbs., with long and deep sides, full ham, thick loin, light shoulders and jowl, and with a high proportion of lean meat in the carcass; an excessive tendency towards early maturity and rapid fattening is to be avoided, otherwise the pigs at the normal age and weight for bacon are liable to be too fat for market.

The type of pig wanted for the pork trade is smaller and younger than for bacon, shorter in body, wider backed, shorter legged, and with a pronounced tendency towards early and rapid fattening.

The four prominent breeds to-day are Large White, Middle White, Berkshire, and Tamworth.

The Large White Yorkshire is one of the largest English breeds whose pedigree records trace back to 1884. The breed is a bacon one, with great length of body, light and neat shoulder, full ham. It stands high on the leg and is of a narrow build. The head is long, the face slightly dished, medium-sized ears inclined forward, but do not hang down over the face. The breed is prolific, hardy, and active, but not remarkably docile. It is late maturing, and crossed with a Middle White or Berkshire-Tamworth sow makes excellent bacon.

The Middle White originated from a cross between the Large White and the now extinct Small White. It breeds true to type; the head is short and wide, the face dished, and snout turned up, ears short and erect. The body is short, wide of back, deep, and on short legs; shoulders prominent and jowl heavy. The breed is very early maturing, sows prolific, and good mothers. Either pure or crossed with Berkshires the Middle White produces good type porkers, and when crossed with Large White or Tamworth makes excellent small bacon.

[Papers Read at Conferences.]

The Berkshire is one of the smaller breeds, but is compactly built and weighs well for its size. The face is short, forehead dished but snout not turned up, ears short and erect, body medium length, wide, deep, and carried on short legs. Loin is thick and ham heavily fleshed and fine of bone. The color is black, with feet and tail tipped with white and white on the face. Berkshires are largely used for crossing. The Mid-White for pork and Large White or Tamworth for bacon.

The Tamworth is red on a flesh-colored skin, snout long and straight, ears are large, rigid, and incline forward. The body is long, fair depth of side, moderate width on long legs. The Tamworth is hardy and prolific. It is late maturing, but the proportion of lean in the carcass is very high.

The crosses are excellent for bacon. Skill and care in the selection of breeding stock are essential to success in pig-breeding, because there are certain qualities and characteristics to which close attention should be directed, whatever the breed and object in view. Of these, one of the chief is temperament. Breeding animals should be active, so that they may have the natural inclination to take sufficient exercise to keep themselves in healthy, but without being restless. They should be docile; nervous and excited sows often occasion great losses among their young at farrowing time. Milking qualities are also important, although too often neglected by the pedigree breeder with his eye on showyard success.

There is a vast difference in the commercial value of litters at weaning time, according to the quantity of milk yielded by the sow.

The number of teats is important; a breeding sow should have 12. Animals with less should not be retained unless they are specially meritorious in other respects. Prolificity is a quality that should always be bred for. If the average litter can be maintained at nine or ten, a good profit can be anticipated, whereas with five or six no measure of success in other directions will make for profit.

The earliest age when a gilt should be put to the boar is eight months, but it is a distinct advantage to wait until 12 months, because the gilt is then grown and may be expected to produce and rear a better litter. Boars may be used sparingly at nine months old.

The period of gestation is about 16 weeks, nursing period 10 weeks, and oestrus generally recurs about the fourth day after the litter is weaned. Thus the whole breeding cycle is completed in about 26 weeks, making it possible for a sow to produce two litters a year throughout her breeding life—normally six years—although longer is not unknown.

The farrowing pen should be one compartment 12ft. square, and if possible, away from the fattening pens, because the squealing often upsets a young sow, causing her to kill her young. A strong rail should run round it at about 1ft. from the wall and 8in. from the floor. The trough should be movable.

During pregnancy the sow does best on free range and ample exercise, receiving only a light ration; about three weeks from farrowing she should be quietly removed to the farrowing pen, which should have been, prior to that, thoroughly cleaned and disinfected, and a good straw litter provided. The ration now should be increased and made more nutritious in order to ensure a full flow of milk. Pollard with 5 per cent. ground peas and skim milk is ideal.

As soon as signs of approaching parturition are observed (*i.e.*, the gathering of litter to make a nest) all long litter should be removed and substituted by chaffed straw, care being taken to disturb her as little as possible. Should the sow show an unnatural desire to devour her young, remove them for several hours.

The sow's rations for the first few days should be light and easily digested, increasing gradually up to 12lbs. or 14lbs. meal per day; restrict green feed. The ration should be so adjusted as to supply fully 80lbs. of starch equivalent and about 15lbs. of digestible protein per 100lbs. dry matter, not forgetting a supply of lime, bonemeal, and charcoal, &c.

[Papers Read at Conferences.]

At three or four weeks the young pigs will seek other food than the dam's milk, and a thin slop should be provided—to which the sow has no access—increasing the ration with growing appetites up to what they will clean up at three or more feeds per day. At six weeks the male piglets should be castrated, opening the scrotum in two places up and down. It is advantageous to starve them 12 hours prior to the operation, as bleeding is then always less.

Where a man is alone an earthenware pipe in the ground one end end, or a hollow log, is very convenient for holding the youngster. The age for weaning depends upon circumstances. The weaners must not be allowed to go back or lose bloom, especially where pork is the objective. These few weeks are important, and frequent feeding and comfortable quarters should be the rule, the ratio of protein to energy value should not be wider than 1 to 5, widening gradually with age to 1 to 10.

Many unsatisfactory results are directly attributable to badly balanced rations; meat meal, peas, linseed, &c., are rich in protein, whilst tares, clover, kales, &c., contain lime and vitamins. Breeders would do well to get tables showing different food values of various foods.

The digestive system of the pig is not adapted for dealing with fibrous and bulky foods, and a large part of the ration must consist of materials with a low fibre content.

At 12 weeks bacon pigs should be grazed and the pasture supplemented according to circumstances, the aim being to keep the pigs in a good, thrifty condition, topping up in the fattening pens prior to sale for three weeks, avoiding such foods as maize or linseed, which produces a soft, oily, and sometimes a discolored fat, also excessive quantities of whey, wet distillery by-products, &c., which tend to make the flesh soft and watery. Soaked barley with limited skim milk produces a fine carcass.

The aim of this paper is to awaken amongst breeders the desire for a general uplifting of the industry, and in this respect it is well to observe the possibilities of exporting surpluses to England. This raises a very pertinent question: What is the use of sending the English consumer a type of carcass he does not like?

MARKETING OF WHEAT.

[S. E. SKEWES, Currency Creek.]

Due to a record wheat production in 1930 the world aggregate for that year being approximately five thousand million bushels, at a time when there was a large carry-over in North America, prices for wheat fell rapidly, until in a space of 18 months values had reduced by more than half.

During this period wheat reached the lowest level of values ever recorded on a world's parity basis, but in Australia the exchange rate rose rapidly in the early part of 1930, and prices here were about on a par with 1893-94, which was the lowest year previously experienced in Australia—the average for that season being 2s. 3d. per bushel at chief shipping ports.

Since wheat is one of the staple commodities of the world, this created a very serious situation, particularly in those countries, such as Australia, in which wheat-growing is one of the principal industries. On account of this unfortunate position having arisen, consideration has been given to the methods adopted for marketing wheat in an effort to evolve a scheme which would be the means of returning a higher price to the grower.

The methods used for the disposal of wheat are practically the same right throughout the world, and the Australian farmer is as well catered for in that respect as those of any other country.

The practice of selling wheat to merchants in the "open" market is the most popular method here, but in four States of the Commonwealth the farmer has facilities available for disposing of wheat through an organisation under the direct control of the wheat-growers, whilst in Queensland wheat is marketed through the agency of a Wheat Board operating on a compulsory basis.

[Papers Read at Conferences.]

Selling wheat on the open market provides the farmer with ready cash, and when the merchant takes delivery of the grain his responsibility ceases, and if a drop occurs in the price of wheat during the remainder of the year the farmer finds himself on the winning side. But it might be that the farmer prefers to hold his wheat until later in the year in the hope of obtaining the benefit of a possible rise in wheat values. Towards this end, the merchant is prepared to help him and will store his grain for him subject to certain conditions. On account of the huge quantity of wheat that has to be stored each year, it is quite impossible for all farmers desiring storage to have their grain stacked separately, so, therefore, the conditions of storage necessarily have to allow the merchant the right of ownership in the wheat so that he can deal in it and dispose of it at his or their discretion. Thus the farmer's wheat loses its identity, but he is still entitled to its equivalent quantity of similar quality grain up to the time that he decides to sell his interest in it.

Under the pooling system the grower is advanced approximately 80 per cent. of the marketable value of his wheat at the time of delivery, and is paid the balance during the year, as the grain is disposed of by the Pool. That Wheat Pools function satisfactorily has been proved on several occasions in Australia, and each of the Pools have on different occasions paid the equivalent or more during a season than the average price paid by merchants. It must also be remembered that the pooling organisation is out to watch the interests of farmers in more ways than that of merely selling his wheat. Being representative of a considerable number of farmers, the board of directors is in a position to approach the Government and other authorities and use its influence on matters affecting the welfare of wheat-growers.

The method adopted by Queensland—and which has been operating for the past 12 years—has proved satisfactory so far as the Queensland wheat-grower is concerned, and it has been suggested that a similar scheme should be introduced for the whole of the Commonwealth. But it must be remembered that Queensland is not a wheat-exporting State like the other States of Australia, excluding Tasmania, and that the production of wheat in Queensland, which in a good season is from 4 to 5 million bushels, is barely sufficient for local requirements. As a matter of fact, something like 3 million bushels have been imported into Queensland during this year, on account of last year's crop being more or less a failure. This being so, the Queensland wheat-grower through the Wheat Board, which consists of five farmers' representatives and one Government nominee, is able to fix a price for wheat supplied to the millers much in excess of world's parity, and the mills work under an arrangement that makes it obligatory on them not to purchase wheat outside of Queensland. Under these conditions the Queensland wheat-grower is a good deal better off than the wheat-growers in the rest of Australia, so much so that for the 1930-31 season he received almost 2s. per bushel more than the average for the remainder of the Commonwealth and in 1931-32 1s. per bushel more. In years previous to 1930-31 the difference was only a few pence in his favor.

To extend such a system to the whole of the Commonwealth would be quite a different proposition, and the ultimate result would be similar to a flour tax, which has been suggested as another means of assisting the wheat-growers.

For the Queensland wheat-grower to benefit to the extent referred to, the consumer of flour in Queensland is compelled to submit to a higher cost of living as the extra price paid to the grower for his wheat is passed on by the miller to the baker and from the baker to the consumer, so that as a State Queensland is really no better off, as it simply amounts to one section of the community benefiting at the expense of the whole.

Now, were this applied to the whole of the Commonwealth with an average annual marketable crop of about 165,000,000 bush., against a local consumption capacity of 35,000,000 bush., cost of flour would be more than doubled if it was desired to obtain

[Papers Read at Conferences.]

for the farmers of Australia the same consideration as the Queensland grower now enjoys, that is, on the basis of 1s. per bushel above world's parity. This is because only about 25 per cent. of the wheat sold would be subject to the fixed price. The other 75 per cent.—which would be exported—would have to be sold at world's parity and the price of wheat sold locally would have to be fixed high enough to allow of the growers of the 75 per cent. exported being paid the same rate per bushel as those growing the other 25 per cent.

Suggestions have been made from time to time that for the Australian farmer to obtain the best results from the marketing of his wheat, the marketing should be in the hands of one organisation operating on a compulsory basis. It has been argued that considerable savings might be effected in administrative costs, and in other ways, were this system adopted. On investigation, however, it will be found that the possible field in which any savings such as this may be effected is very limited indeed. Even with the reduced overseas freight operating as at present, practically 75 per cent. of the cost of shifting wheat from farmers' waggons in Australia to Liverpool is made up of rail and shipping freights, and no reduction could be made on those items even if all the wheat was handled by one organisation. Slight savings may be made in overhead expenses and receiving charges in the country, but it is not likely that these would aggregate more than a fraction of a penny per bushel. Against this possible saving there would be certain disadvantages, which, in the long run, may cost the grower a good deal more. Under the present system of marketing wheat, the merchants are in competition not only with each other, but also with the Pool, and this means that every effort is made by each party to cut all expenses to the absolute minimum, and is also an incentive to obtaining the highest price possible for the grower, for the merchant knows that if he does not pay as high an average price as the Pool he will lose the support of the farmers, and the Pool, on the other hand, knows that if it cannot satisfy its members, it will very soon be forced out of business. Competition is in the very best interests of the wheat-grower. Were compulsory Pools established, this competition would be entirely eliminated and the compulsory Pool would have a 100 per cent. monopoly, which would be most undesirable and even dangerous. Competition is provocative of efficiency in the marketing of wheat as in any other business.

It has been stated that the Australian farmer is at a very great disadvantage due to the distance he is from the principal markets of the world—those of Europe. This is so to a certain extent, but with the possibilities existing in the East and Asia for extended wheat and flour trade, this disadvantage will not be felt so keenly. Wheat-growers in Canada have very high charges to meet on their export wheat, and the cost of shifting wheat from an average railway station in Western Canada to Liverpool is even more than it is from an average station in South Australia to Liverpool. The higher charges from Canada are mainly due to longer rail transit, Lake freight from Fort William to Montreal, and consequent extra handling.

Where the Australian farmer is at an unfair disadvantage is in the matter of loading charges, &c., at the various ports. The loading charges and port dues for wheat at Australian ports are higher than those in any other wheat-exporting country of importance, and in 1930 were double those existing in Canada, United States of America, South America, and India. In addition to these charges, wheat exported from South Australia is subject to an export wharfage charge of 1½d. per bag.

It would appear that for the Australian farmer to seek an improvement in his present unsatisfactory position he will not only have to look at the marketing of his wheat, but more so to the other side—that of the cost of production. Australia is dependent on the outside world for the disposal of her wheat crop, and since no one country is in such a position that it can fix prices of its own making for the export sale of its wheat, it follows that the most the Australian farmer can expect for his grain—without taxing his own community by means of local fixed prices, flour tax, bounties, &c.—is world's parity.

[Papers Read at Conferences.]

Had the costs of producing wheat fallen in proportion to the reduced price offering for wheat, the farmer would have had no real cause for complaint, but this did not occur, and since Australia is dependent—more now than ever before—on her primary producers, this section of our people has a very definite right to expect reasonable consideration, at least from those who at present are prospering at their expense. If our protected industries, and our Governments are not prepared to step into line and do their part towards reducing the costs of production, the wheat-grower will have to be supported artificially, and be paid bounties in some way or other to make up the deficiency between what the world is prepared to pay for his produce and what it costs him to produce it.

HILLS BRANCHES, McLAREN FLAT, AUGUST 24th, 1933.

TOBACCO CULTURE.

[R. G. MORPHETT, Kangarilla.]

After selecting the block for tobacco it should be ploughed deeply, the ploughing being done in autumn, exposing the soil to sweeten it. The second ploughing need not be so deep as the first (about 4in.). The ground must be kept well worked to produce a fine tilth and conserve moisture, right up to planting the seedlings.

SEED BEDS.

It is most essential in the production of a good crop of tobacco to have a good supply of early plants. It is better to have a few thousand more than too few. In making the seed bed, select a piece of rich well-drained land where it receives the most sun, and as near to water as possible. The bed should be 30ft. long by 3ft. wide, and 3ft. between each bed. A bed this size will produce enough plants for 1 acre. The beds should be raised 6ins. by putting the earth between the beds that form the pathway, on to bed in which it is intended to sow the seed. Place boards around about 6ins. high. After the soil has been worked to a very fine tilth, a manure of 9lbs. 45 per cent. super and 3lbs. of blood manure to each bed is a very good mixture. The bed should then be sown. One 12-gauge cartridge shell full of tobacco seed is enough to plant one bed. It should be mixed with about a 2lb. jam tin of finely sifted ashes and shaken lightly over the bed. After the seed is sown, cover the beds with a covering of 8oz. hessian. For early seedlings, start sowing beds the second week in August.

When young seedlings have produced the fourth leaf, they can be forced on by giving a dressing of a handful of nitrate of soda to a kerosene tin full of water. It is most essential not to let the seed bed become dry. A light watering three times a day is necessary in hot weather.

TRANSPLANTING.

Now that the ground is ready, sow the manure and cultivate it into the soil. It is now necessary to sow a cutworm bait of 1lb. of paris green to 30lbs. of bran made into a mash, sweetened by mixing a little sugar or treacle in the water. This should be sown about three or four days before transplanting the seedlings and after sowing the manure.

When planting the seedlings, place them in rows about 3ft. by 3ft. This will give about 5,000 to the acre. The plants should be as uniform in size as possible, the aim being to have an even growth and an even maturity. After being drawn from the bed, the plants should not be exposed to the sun before planting, but placed in boxes and kept well shaded. After making a hole with a dibber into which the roots are inserted, the soil must be pressed tightly around the roots of the young plant.

[Papers Read at Conferences.]

This is very necessary in order that the roots can obtain moisture needed to sustain the plant until it re-establishes itself. After planting—if the weather is hot—the plants should be covered, the latter being removed after the plants have established themselves. Bracken fern makes a good covering.

For good growth it is necessary to keep the field free from weeds and keep the soil in good condition. As soon as the young plants are established, the earth around them should be loosened by hoeing, care being taken not to injure the roots. Cultivation should be done frequently, both around the plants and in the rows, especially after a shower of rain. This will help to conserve moisture and also help the growth of the plants. During the season, insects become a pest and "worming" must be carried out regularly. Small caterpillars do an enormous amount of damage to the leaves. The plants should be dusted with arsenate powder to keep them in check. So far as possible, the caterpillars should be removed by hand picking.

TOPPING AND PRIMING.

When the plant shows its flower head it should be removed with three or four of the smaller leaves. If, on the other hand, the plant is allowed to go to seed, the leaves will be papery and will not develop into such good leaves. Fourteen to sixteen good leaves should be left, not counting the bottom one, which should be taken out at the time of topping. This is known as priming, and permits free circulation of air and distribution of light.

The bottom leaves if allowed to remain on the plant become worthless by constant whipping on the ground. No fixed rule can be given as to the number of leaves to be left on a plant; this depends on the development of the plants and the time left for ripening. The shorter the season the less leaves, the longer the season the more leaves.

SUCKERING.

Shortly after topping, suckers or lateral shoots make their appearance at the butt of the leaves and at the base of the stalks. These must be promptly pinched out while they are still young. If left, they become tough and develop flowers and seeds at the expense of the leaves. Suckering is a long job because the plants have to be gone over about every 10 or 12 days—the stronger the plants the more suckers there are.

VARIETIES AND HARVESTING.

Some of the varieties which I have grown and which have given good results are Hickory Pryor, Conqueror, White Stemmed Orinoco, Warne, Hester, Gold Leaf, Lacks, and Homestead.

This is the last operation in the field. Like topping, this operation requires good judgment and experience, for a good crop of tobacco can be spoiled in the final work by bad picking. After topping the bottom leaves will commence to ripen. Those grown in sandy soil change their color from dark to pale green. The leaves grown on heavier soil become mottled with yellow patches.

When ripe the leaves are broken from the plants, removed to the barn, and there fastened on sticks which are hung in the barn ready for curing. It is important to see that the picked leaves are removed immediately from the field to the shed or covered, as they soon become scorched by the sun.

DEHYDRATION.

[H. C. PLATTS, McLaren Flat.]

Dehydrators are used for many purposes; drying green bricks before baking, drying timber, &c., and it was only a short step before fruit and vegetables were also dried artificially.

[Papers Read at Conferences.]

There are several types of evaporators and dehydrators. The term evaporator, which to-day refers more particularly to the use of artificial heat, depends on circulation of air by natural draft. Such driers cost less to build than forced draft driers, but their operation is less efficient and more expensive. It is difficult to obtain even drying, and a long period of drying is required. The heated air after passing over the fruit is lost.

VACUUM DRIERS.

The vacuum driers will dry material more rapidly and at lower temperatures. The chief objections to this type are the high cost of construction and operation. Dehydrators or forced draft driers consist of a long tunnel in which the material and air move horizontally. The fruit is placed on trays and then placed on trucks. The loaded trucks are introduced one end and after passing in a continuous train through the tunnel, come out of the other end, by which time the fruit is dry. This type of machine is both efficient and economical.

Proper dehydration returns a clean, thoroughly dried product fully retaining the quality of the original fruit and answers the modern demand for sanitary production of foods. During unfavorable drying weather, prunes undergo a partial fermentation. This fermentation is caused by the sugar in the prunes fermenting with the aid of ever-present yeasts, and changes into alcohol and carbon dioxide gas. Both these compounds are volatile; they evaporate into the surrounding air and cause a loss in weight which is in proportion to the extent of fermentation. The temperatures normally used in dehydrators are above the temperatures at which the fermentation organisms act and consequently such losses are prevented by dehydration.

Even if the weather conditions are ideal for drying, prunes will also suffer a loss in sugar by respiration. The sugar turns to carbon dioxide gas and water, compounds that evaporate from the fruit.

Further losses are caused by bad drying conditions. Prunes will lose color and flavor through fermentation. Such injury does not prevent the sale of prunes or fruit, but definitely lowers the quality and market value. Also the prunes do not dry promptly, and the result is "bloaters," "chocolates," &c. The greatest advantage of the dehydrator lies in the fact that labor is used more efficiently. In sun drying and dehydrating the prunes are dipped and trayed; in sun drying the prunes are moved to a considerable distance on to the drying ground and the trays are spread, one at a time, on the ground. The prunes then must be stirred to promote even drying. When dry, the trays are stacked on the ground and then carried into the packing-shed and the prunes are put into sweat boxes. In case of rain, labor is further increased because of additional stacking and unstacking. In contrast to these laborious operations, prunes for dehydration are quickly placed in the dehydrator, a truck at a time, and when dehydrated, are removed, cooled, and the prunes emptied into sweats.

Since the dehydrator dries the fruit at a steady rate, the workers are stimulated to keep pace with this rate. This stimulus is less evident in sun-drying. Fewer workers are needed for dehydration and each does more effective work than in sun drying. The growers' greatest problem is adequacy and efficiency of labor and a dehydrator is of distinct value in solving this problem.

Dehydration produces fruit of equal or better quality than sun drying, results in a greater yield and size of fruit, provides insurance against rain damage losses, and the total cost of operating an efficient dehydrator is no greater than for a sun-drying ground of equal capacity.

[Papers Read at Conferences.]

MORE ABOUT THE DAIRY FARM.

[G. CONNOR, McLaren Flat.]

The economies of dairy production have needed the greatest attention on the part of those engaged in the industry perhaps dating back to the time when it was first realised that the food supply for man could be greatly augmented by the expedient of taking the milk of animals. The food that is intended by Nature for the sustenance of their young—milk, butter, cheese, whole milk—was found very nutritious for humans of all ages. Butter is very valuable in conjunction with cereals, &c. Cheese can be stored up and improves with age, having long keeping qualities, and thus enabling the people to provide for times of scarcity. Biblical history records many evidences of dairy practice. Cattle of all species, sheep, goats, deer, horses, asses, and camels have all been recruited for the purpose. There is no doubt that it soon became evident to the people in those far-off times that the better nourished animals were the most profitable. The people listened to stories of lands that were abundantly blessed with cows and wine—lands flowing with milk and honey; of better pastures, and men were filled with longing to place their flocks and herds in better conditions so that their returns would be satisfactory.

They certainly would have valued the heavier producing animals, and we should record appreciation of the work of the early pastoralists keeping their animals up to a standard that has endured to the present time and delivered them to the present generation for their use in such a wonderful state of preservation.

The present conditions of the world markets, keen competition, and the difficulty to find an outlet for dairy produce with low prices make it quite clear that if the dairy farmer is to keep in his business he must use every means that offers a saving and so balance his accounts. The herds must not include any unprofitable cows. Select a breed that suits local conditions and one for which the farmer has a fancy. Do not cross breed more than once. Breeding from crossbred beasts produces mongrels. There may be some wonderful producers among the latter, but the percentage is too low. The progeny splits into so many different types. Even the first cross may bring disaster. Heavy milking strains with a low fat content crossed with a high fat content breed and lesser quantity of milk appear to give the quantity and quality, but there is another very likely result. The low fat content of the former and the low quantity of the butter—such an animal would be a very bad proposition.

Too often we use animals of a high producing nature on both sides, but the result is a disappointing type of beast. Can it be that there is an off-generation? A plan of Nature to keep the balance between a robust fleshy body without the capacity to secrete milk beyond a safe point, and the more finely cut cows that can be stimulated to give a large quantity even to the point of exhaustion and even death.

Many champions fail to produce their like. The best that can be done is to persevere with those types that seem to possess the power to produce heavily, coupled with a constitution that will not be impaired in consequence.

The food supply must be good and economical. There is nothing to recommend the policy that so many adopt of feeding high-priced foods to create records, unmindful of the fact that such production has a two-edged effect. We are only getting a small net return and unloading a large quantity of goods on to an already glutted and depressed market; production should be brought back to an economical limit. When the dairyman has to purchase such large quantities of high-priced foodstuffs he is overstocking his holding. He must produce more of his cattle food on the farm. See that the pastures carry the stock that they should by bringing them to a fertile state, cut the holding into small paddocks, lay down the land with suitable grasses, and where necessary, shut a few acres up and cut for hay. Do not forget superphosphate.

Take an interest in your calling. Look over the herd often, and to avoid heavy losses learn a little about veterinary practice. Try to deliver the raw material to the manufacturer in good clean condition; assist him to assist you.

MANURING OF APRICOT TREES AT LIGHT'S PASS, - SEASON, 1932-33.

[By J. B. HARRIS, Dip. Hort., Horticultural Instructor.]

An experiment in the manuring of apricot trees with superphosphate, and with superphosphate and sulphate of ammonia, which was commenced in September, 1928, and which has been previously reviewed in the *Journal of Agriculture* for March, 1931, and July, 1932, has been continued during the past season, and the additional record listed below has been obtained.

Although a severe frost occurred in the district in October, 1932, it was mainly the lower lying areas which were affected and, as will be seen from the crops harvested, the test plot escaped serious damage.

The ratio of average crop harvested per tree from the different manured and check plots tallies approximately this year with results obtained during seasons 1928 to 1931, and with the average of results obtained in 1932, when Plots C. and D. showed a conspicuous shortage of crop which it was suggested may have been due to dry conditions and the shape of the plot (see *Journal of Agriculture*, July, 1932). Thus, trees which received no manure have so far shown a tendency to produce more fruit than those manured with superphosphate, and trees manured with superphosphate and sulphate of ammonia have shown a tendency to produce more fruit than those which received no manure.

Unfortunately the number of trees of even type on this plot is not large enough to permit of sulphate of ammonia being tested alone without eliminating one of the other tests which it is proposed to carry on in their present form for a further period of years.

	1928-29.	1929-30.	1930-31.	1931-32.	1932-33.	Average 1928-29 to 1932-33.

STATE OF SOUTH AUSTRALIA.

WHEAT PRODUCTIVITY CLASSIFICATION, 1932-33.

[W. L. JOHNSTON, Government Statist.]

With a view to ascertaining the extent of acreage producing very high and very low returns of wheat per acre, all wheat farms have been classified according to their productivity per acre. The accompanying return sets forth comparative details for the three seasons 1930-31, 1931-32, and 1932-33.

The total yield for 1932-33 was 42,429,614 (48,093,102) bushels, averaging 10.43 (11.81) bushels per acre, and the Agricultural Areas Rainfall April-November was 14.70 (13.27) inches. 2,323 (3,488) farmers or 16.30 (24.38) per cent. harvested 18 bush. per acre, and upwards producing

TOMATO SPOTTED WILT ON TOBACCO.

By GEOFFREY SAMUEL, Plant Pathologist, Waite Agricultural Research Institute,
University of Adelaide,

and

J. G. BALD, Assistant Plant Pathologist, Division of Plant Industry, Council for
Scientific and Industrial Research.

It is not generally realised even by tobacco growers themselves that the spotted wilt disease of tomatoes also attacks tobacco. In fact, although it usually occurs only on isolated plants, it is probably the disease which is most frequently met with in South Australian tobacco crops. (This, of course, is apart from the Downy

Fig. 1.—Field plant naturally infected with spotted wilt. Late stage showing drooping and death of lower leaves, as well as necrosis on younger leaves.

Mildew, or “blue mould” disease, which occurs mainly in the seedbeds.) Occasionally crops have been seen in which more than 5 per cent. of the plants were infected, and in one case more than 30 per cent. of the plants were diseased.

Since, therefore, spotted wilt is potentially a serious disease of tobacco as well as of tomato it is advisable that growers should be able to recognise it. The following brief description of the disease, with illustrations, has therefore been prepared.

THE CAUSE OF THE DISEASE.

The disease is caused by an infectious virus which is transmitted in the field and inoculated into plants by two species of thrips, *Frankliniella insularis* and *Thrips tabaci*. No special field work has yet been done on its occurrence on tobacco, but the identity of the disease with tomato spotted wilt and the possibility of its transmission to tobacco by thrips have been proved in the experimental glasshouse.*

It is probable that field spread in tobacco crops occurs in the same way as in tomato crops. The first infections come from infective thrips which have over-

Fig. 2. Portion of tobacco field, showing four plants in the foreground naturally infected with spotted wilt at an early stage.

wintered, or which have recently hatched on some infected garden or weed plant. Healthy adult thrips cannot pick up the virus by feeding on a diseased plant, but they usually lay eggs while feeding, and the young which hatch from eggs laid on a diseased plant acquire the virus in the larval stage. After pupation and emergence as adults the infection is retained in these insects for life, and any healthy plants on which they subsequently feed may be infected.

THE SYMPTOMS.

The symptoms shown by tobacco plants infected with spotted wilt are essentially necrosis or dying of the tissues of the younger leaves in very variable patterns. These include (1) circular necrotic (dead) spots of various sizes (Figs. 3, 8, 10);

*Bald, J. G., and Samuel, G.: Coun. Sci. and Ind. Res. Bul. 54.

Figs. 3-5.—Leaves from field tobacco plants naturally infected with spotted wilt. Necrosis brown; in spots, or in lines along veins.

Figs. 6-8.—Leaves from field tobacco plants naturally infected with spotted wilt. Mottling of lower part of leaf, with whitish necrosis along fine veins and laterals, or in spots.

(2) necrotic areas along the lateral veins, usually on the lower half of the leaf and often on one side only (Fig. 5); (3) a characteristic mottle effect due to the invasion of all the fine veins in the lower half of the leaf—there being usually in this case a coarser pattern bordering the veins immediately above the fully-invaded area (Figs. 6, 7, 9); (4) various combinations of these symptoms and irregular patterns (Figs. 4, 8). The color changes vary from yellowish-green in the mottled area to reddish-brown or white in the necrotic spots and lines.

The top of an infected plant ceases growth, and in the early stages is frequently bent over slightly to one side. Later dark sunken streaks may appear on the stem, or when the stem is cut across dark necrotic areas of discoloration, later forming cavities, may be seen in cortex or pith.

In the field infected plants remain at a standstill for some weeks, and later all the leaves gradually droop and die, and the plants are slowly killed (Figs. 1, 2).

Figs. 9 and 10.—Leaves from tobacco plants experimentally infected in the glasshouse with tomato spotted wilt; showing two patterns of necrosis resulting from systemic invasion by the virus.

Occasionally, instead of the gradual dying a somewhat distorted secondary growth commences, and then almost normal leaves may be formed again. These, however, are always liable to a further onset of necrotic symptoms.

Frequently the primary lesion due to the development of the virus at the site of inoculation can be seen on field plants on one of the lower leaves. This is the point where the plant was infected by thrips feeding. The primary lesions can be better observed in the glasshouse, however, and two late stage types are shown in Figs. 11 and 12.

CONTROL.

Experience with tomato spotted wilt has shown that insecticidal sprays or dusts do not provide an adequate control. This is because so few thrips may be responsible for the spread of quite a considerable amount of virus infection. At present the best recommendations which can be given are:—(1) Avoid growing tomatoes and susceptible garden flowers such as Iceland poppies, nasturtiums, zinnias, or dahlias in the vicinity of seedbeds or field. Also keep down weeds of the tobacco family such as black nightshade. (2) Remove and bury infected plants at frequent intervals, for it is thrips which hatch on these plants which spread the infection.

Figs. 11 and 12.—Primary infection lesions of spotted wilt on tobacco at a late stage (mechanical inoculation). In Fig. 11 the spread of virus at cool to moderate temperatures is indicated by necrosis of the veins. In Fig. 12 there is less necrosis owing to higher temperatures.

POSSIBLY RELATED DISEASES.

Technical Note.—Attention may be called to the similarity in symptoms between spotted wilt on tobacco and the diseases described in the following papers:—

- (1) Böning, K. Zur Aetiologie der Streifen und Kräuselkrankheit des Tabaks. Zeits. für Parasitenkunde 3: 103-141. 24 figs. (1931).
- (2) Jochems, S. C. J. Een nieuwe virusziekte van Deli-Tabak, de Rotterdam B-ziekte. Bull. van het Deli Proefstation 26: 5-23 (1928).
- (3) Moore, E. S. A virus disease of tobacco in South Africa. Nature 129: 544 (1932).

Until further details on insect vectors, host range, and virus properties of these diseases are published no decision can be reached as to their identity or otherwise with spotted wilt.

THE DOG: ITS AILMENTS AND DISEASES.

The Library of the Department acknowledges the receipt of a book, "The Dog: Its Ailments and Diseases," by B. D. McMichan, R.V.S. The opening chapter deals concisely with the general care and feeding of dogs, and contains much sound practical matter on which every dog owner should be well informed. Simple indications of disease, medicines and their administration, and nursing, form the subjects of other brief chapters. The bulk of the book deals with the various ailments of the dog in a practical manner. Being written in a clear, easily readable style, the book is one which should be of practical service to dog lovers. Published by Messrs. Angus & Robertson, Sydney. Price 4s. 6d.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

CONFERENCE OF HILLS BRANCHES.

Delegates from the Longwood, Balhannah, Blackwood, Kangarilla, Cherry Gardens, Clarendon, Lenswood and Forest Range, and McLaren Flat Branches held their Annual Conference at McLaren Flat on August 24th. Messrs. H. N. Wicks (Advisory Board of Agriculture), W. J. Spafford (Deputy Director of Agriculture), H. B. Barlow (Chief Dairy Instructor), R. Fowler (Manager Blackwood Orchard), E. Leishman, J. B. Harris (District Instructors), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary Agricultural Bureau).

Mr. C. Robertson presided and the opening address was delivered by Mr. H. N. Wicks. The following papers were read and discussed:—"Dehydration," H. C. Platts (McLaren Flat); "Dairying," G. Connor (McLaren Flat); "Tobacco Culture," R. G. Morphet (Kangarilla). Conference also discussed the top dressing of pasture lands, cover crops for orchards, pruning apricot trees, silver leaf of the plum, and carried the following resolutions:—"That the 1934 Conference be held at Coromandel Valley under the auspices of the Blackwood Branch;" "That the Government be asked to rescind the rule which demands the payment of 2s. 6d. per annum for the *Journal of Agriculture*;" and "That the Government be asked to abolish the licensing fees for dairy cows and bulls."

CONFERENCE OF SOUTHERN BRANCHES.

The Annual Conference of Branches of the Agricultural Bureau in the Southern Districts met at Goolwa under the auspices of the Currency Creek Branch on Thursday, August 17th. Delegates were present from the Murray Bridge, Milang, Strathalbyn, Rockwood, Finniss, Hindmarsh Island, Hartley, Langhorne's Creek, Inman Valley, Port Elliot, Rapid Bay, Currency Creek, Mount Compass, Jervois, and Belvidere Branches.

The Department of Agriculture was represented by Messrs. P. J. Baily (Advisory Board of Agriculture), W. J. Spafford (Deputy Director of Agriculture), H. B. Barlow (Chief Dairy Instructor), C. F. Anderson (Government Poultry Expert), R. Hill (District Instructor), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary Agricultural Bureau).

Mr. A. Saltmarsh presided, and the opening address was delivered by Mr. P. J. Baily. The following papers were read and discussed:—"The Future of the River Murray," J. P. Colebatch (Port Elliot); "Essentials in the Personality of the Farmer," W. E. Hargreaves (Port Elliot); "The Clydesdale Horse," A. M. Fuller (Port Elliot); "Pig Breeding and Management," B. Casley (Milang); "Marketing Wheat," S. Skewes (Currency Creek). The agenda covered a wide range of subjects relating to fodder crops, stock diseases, and management.

During the session devoted to Free Parliament the following resolutions were adopted:—"That the 1934 Conference be held at Strathalbyn;" "That it be a standing order for the Southern Conference that the invitation for the place of next Conference be given just before lunch and the vote taken immediately after the adjournment;" "That at future Conferences resolutions and questions on agenda be dealt with immediately after lunch, irrespective of any papers that may have not been read;" "That this Conference place on record its appreciation of the way in which late Fruit Inspector Beaumont carried out his duties;" "That it be a recommendation to the Government to have the tare of cream cans stamped on the can and the lid;" "This Conference

requests the Government to take steps to prevent the sale of dairy cattle that are affected with abortion;" "That the age limit for the registration of bulls be extended to nine months in place of six months;" "That as, apparently, the rule *re* new members is not giving satisfaction, it be rescinded, and the following substituted: 'That all members except life members and Branch Secretaries pay the annual subscription of 1s. if they do not require the *Journal*, or 2s. 6d. including *Journal*. Members whose subscriptions are unpaid on January 31st be struck off;" "That instead of resolutions which are carried at Conferences being sent before the Advisory Board of Agriculture, a deputation be appointed at the Conference to place them before the Minister of Agriculture."

At the Evening Session Mr. C. F. Anderson (Government Poultry Expert) spoke on several phases in the Poultry Industry.

PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR SPRING, 1933.

EGGS FOR HATCHING AND DAY OLD CHICKENS

WHITE LEGHORNS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, £2 per 100.

DAY OLD CHICKENS.—15s. per dozen; £4 per 100.

BLACK MINORCAS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, £2 per 100.

DAY OLD CHICKENS.—15s. per dozen; £4 per 100.

**Free on Rail,
Salisbury.**

DELIVERY.—CHICKS—August and September.
EGGS—July to September.

Intending breeders should recognise the importance of establishing their flocks with only the very best of stock also, pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2ozs., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

DAIRY AND FARM PRODUCE MARKETS.

MESSRS. A. W. SANDFORD & Co., LIMITED, reported on September 1st, 1933.

BUTTER.—Although there was a seasonal increase in production throughout August, the quantity manufactured in this State was considerably less than for the corresponding period of last year. With the splendid rains received, however, during the past few days, a great fillip was given, and within the next few weeks the supplies will no doubt move forward very rapidly. The heavy rains were very opportune, as in some areas the pastures were very backward indeed. Recent reports from London indicate that the markets are continuing fairly steady, and the demand for the South Australian butter was being maintained. Values, therefore, in the local market have continued on a fairly even keel, and consignments cleared from week to week. Choicest creamery fresh butter in bulk, 1s. 2½d.; prints and delivery extra. (These prices are subject to the stabilisation levies.) Store and collectors, 7½d. to 8d. per lb. at store door, less usual selling charges.

EGGS.—The supplies are now coming along very freely, although up to within a week ago the production was not moving forward so rapidly as last year, but it appears now that a lot of the leeway will be made up, judging by reports from various country centres. With packing for export now in full swing, there is keen competition for prime quality, clean, full-sized eggs which will pass the graders, and rejects and pulp eggs are not so greatly sought after. Ordinary country eggs, hen or duck, 5d. per dozen; selected export quality eggs, 1½ozs. and over, 9d. to 10d. per dozen.

CHEESE.—The factories are now manufacturing export size cheese, as well as those for local use, and within the next few weeks it will be necessary to ship quantities to clear the surplus. Local and Western Australian buyers purchased regular quantities each week, and still continue to do so, so that the floors have been kept nicely cleared, and values are steady. New makes, medium and large, 7½d. to 8d.; loaf, 7½d. to 8½d.; semi-matured and matured, 9½d. to 10½d. per lb.

BACON.—Curers during the month under review were kept working at full pressure to cope with the supplies of live hogs available, and the sales of bacon were greater last month than for some time past, as not only was there a good local demand experienced, but also interstate trade was negotiated from week to week. With the higher prices ruling for the live hogs, the supplies have increased, so that there are heavy stocks of bacon in process of curing. Lard continues in shorter supply than requirements can absorb, and therefore values have firmed. Best local sides, 9½d. to 9½d.; best factory cured middles, 10d. to 11d.; large, 9d.; rolls, 8½d.; hams, 11½d. to 1s. per lb.; cooked, 1s. 1d. to 1s. 2d.; lard, prints, 7s. per dozen.

ALMONDS.—Active demand was experienced, and still continues, for all grades of almonds, but consignments received have been only limited, as many growers have ere this quitted the bulk of their stocks. Kernels have been short in supply, and are wanted. Softshells and Brandis, 8½d. to 9½d.; hardshells, 5d. to 5½d. per lb.; kernels, 1s. 11d. to 1s. 11½d. per lb.

HONEY.—Some interstate trade was done throughout the month, and local buyers operated more freely, so that consignment stocks were considerably reduced throughout the month. Prime clear extracted in liquid condition, 3d. to 3½d. per lb.; lower grades, 1½d. to 2½d. per lb.

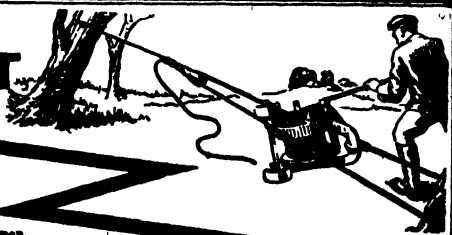

BEEWAX.—All lots met with ready clearance, and at date stocks were very short. 1s. 0½d. to 1s. 1d. per lb., according to sample.

LIVE POULTRY.—Exceptionally good markets ruled for poultry during the last few weeks, and although the quantities received were extensive, there was a good winter sale throughout, and with the close proximity of the Royal Show in Adelaide poulterers are now replenishing stocks in expectation of an influx of visitors to the city. We advise consigning. Crates loaned on application. Prime roosters, 3s. 6d. to 4s. 9d.; nice conditioned cockerels, 2s. 10d. to 3s. 5d.; fair conditioned, 2s. 3d. to 2s. 9d.; chickens, lower; heavy-weight hens, 2s. 9d. to 3s. 6d.; medium hens, 2s. 3d. to 2s. 8d.; light hens, 1s. 10d. to 2s. 1d.; couple of pens of weedy sorts, lower; geese, 3s. to 4s.; goslings, lower; prime young Muscovy drakes, 4s. to 5s. 6d.; young Muscovy ducks, 2s. 9d. to 3s. 4d.; ordinary ducks, 1s. 9d. to 2s. 8d.; ducklings, lower; turkeys, good to prime condition, 8½d. to 11d. per lb. live weight; turkeys, fair condition, 7d. to 8d. per lb. live weight; turkeys, fattening sorts, lower; pigeons, 3d. to 4½d. each.

POTATOES.—Local new, 5s. 6d. per cwt.

ONIONS.—New season's, 4s. 6d. per cwt.

TEARING THEM OUT.

is the regular job of the Monkey Grubber; in fact it was born to the work.

TREES and STUMPS. It matters not, they say, how big, with roots intact, a thorough job can be done. Run to the job like a horse, break, and worked in the same manner as a team is roved, it develops the power of 200 men, progressively applied, and always under perfect control.

In any position, so long as the operator has room for a swing, the machine is efficiently worked. An Automatic Gear allows a load to be heaved or released at will. Besides the great power and portability there are embodied other labour saving features, such as special rope couplings, rope shortener, smooth block, etc.

Agriculturalists in Australia, New Zealand, Great Britain, South Africa, the Americas, as well as Planters in India, China, Central Africa, Fiji, the East and West Indies, recognized its merits and applied its help.

THE "MONKEY" GRUBBER

is fabricated from material mined and made within the Empire, by Empire craftsmen, to assist with the full and efficient development of Her Majesty's resources.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[Branch Secretaries are reminded that the following are exempt from payment of the Annual Bureau subscription:—Life members, Branch Secretaries, members appointed before August 1st, 1930, and new members who reside in the same house as (a) a life member, (b) Secretary, or (c) another member who already subscribes.

The subscription for all other members is 2s. 6d., commencing from August 1st in each year, provided that—subject to the above exemptions—nominations forwarded during the months of January to June must be accompanied by a payment of 1s. 6d. each nomination for that period.]

(PETERBOROUGH TO FARRELL'S FLAT.)

KOOLUNGA (Average annual rainfall, 15.40in.).

July 4th.—Attendance, 10.

The Hon. Secretary read the annual report and balance-sheet, and officers were elected for the ensuing year. Mr. H. Spencer read a paper, "Where Does Economy Begin on a Farm?" He stated that, with the value of farm produce at its present level, and the cost entailed in producing the same, it was almost impossible to make ends meet. One was often at a loss to know just where economy began or ended, and

whether money spent for extra labor or plant was really economy or extravagance. Economy lay not so much in rigidly curtailing all expenditure as in spending wisely, and putting money into farming operations that would show more profit. Often it was false economy to persevere with harvesting machinery when it had become badly worn, since, in the course of a few weeks' work, a farmer could easily lose sufficient wheat to pay a substantial deposit on a new machine. The same applied to employing men in the harvesting operations who were careless about their work; and it applied to every phase of work in connection with the farm. In all classes of work implements and machinery should be well cared for, and so set as to do the best work by offering the least resistance. Cultivators and ploughs could often be made to pull two horses lighter if the shares were set at a correct angle for cutting their way through the ground, instead of dragging through it. Thus a saving in horseflesh—or, if working a tractor, a saving in fuel and oil—would be effected. Stump-jump cultivators and ploughs should have sufficient draught on them to prevent the frame of the tine riding on the frame of the implement practically the whole time unless resistance was offered by stones, stumps, &c. Tines that were lifting partly out of the ground all the time so that the shares were riding on the points offered greater resistance to the power which was pulling the implement, and thus did poorer work. The life of the cultivator and plough axles could be doubled if protected from dust and dirt, especially in undulating country. No matter how well the box of a wheel might fit the axle, there was always room for dust to get in on the inside end unless further protection than the manufacturers supplied. He recommended binding a piece of bag firmly round the arm of the axle until practically flush with the collar on the hub of the wheel, and then binding another piece around it so that it overlapped the collar or the box. If it were then soaked with waste oil it would be practically dust-proof, and would eliminate the wear on the axles by 100 per cent. Such practices took but a few minutes, but gave years of service and were real economy. It paid handsomely to try a few different brands of cultivator shares at times, because some would be found to have 100 per cent. more wear than others, through being made of better or harder tempered steel. A blacksmith's shop on the farm was essential, and good economies could be made in that direction. One should never delay the working of the land to do the jobs of the blacksmith unless compelled to, but an eye should be kept on implements, &c., and when it was seen that a job required attention it should be done on the first wet day. By adopting that method there was no time lost when the land should be worked, and it was a pleasure to do such jobs on wet days. A large saving could be made by plating the plough shares. If the shares were plated underneath the same sockets would last for years, and the draught of the plough would be lighter. When fallowing was finished the opportunity should not be lost of working fallows after a rain. Some farmers neglected that part of the work at times because they thought that rains were too early and they might have to go over it twice. That was a bad policy, and it often ended up in having to work the land dry, when it could not be worked to the same advantage. After seeding it was a good plan to take the seed box off the combine and put it in the shed or on a stand and cover it over with iron, thus protecting it from the weather, and making the combine, which was used fairly extensively for cultivating, several cwts. lighter to pull. Harvesters, &c., should be thoroughly overhauled and put in order in the slack periods, because valuable time might be lost in the fields. When harvesting was finished the machine should be taken straight to the shed and placed under cover. A good practice was to make a note of anything that required replacing or renewing prior to starting next year's harvest.

BARLEY

We have large Overseas Representation, and are in constant touch with the World's Markets, and strongly advise Growers, before selling elsewhere, to submit samples to us for valuation.

Delivery taken at any Railway Station, Siding, or Shipping Port.

F. W. HANCOCK & CO.,

CRANBROOK CHAMBERS, BENTHAM STREET, ADELAIDE.

TELEPHONE: CENTRAL 4855 and 4856.

Harness should be kept well oiled with good neatsfoot oil, as leather soon perished when allowed to become hard and dry. Good oil and a good oilcan should be a golden rule with all farmers. Oil was much cheaper than bearings. It was no trouble to get a man to oil a machine well if he had a good can to do it with, and a few shillings spent in that direction might mean pounds saved in bearings. It was often good economy to have an assortment of nuts and bolts on the farm, and a pound or two spent in that direction might save miles of travelling. A good supply of scrap iron would be most useful at the farm smithy. A pound spent to secure an old machine at a sale would often return ten times its value in bolts, iron and bearings. A good set of wrenches and tools saved time when executing repairs, and a few pounds spent in that direction was a wise investment. One should always endeavor to work with a system, and keep up with seasonable jobs, especially field work. The work for the next day should be planned the night before, so that there was no time lost in wondering what to do the next morning. All farmers should be members of the Agricultural Bureau, and by interchange of their ideas, methods, and tests, help themselves and their fellow farmers. (Secretary, I. J. Jones.)

BLACK SPRINGS.

June 6th.—Attendance, 7.

PIGS AS A SIDE-LINE.—Paper contributed by Mr. E. Siegert:—"At the present time pigs are not very profitable, but if properly cared for, will help the revenue of the farm. The class of pig should be given first consideration. I prefer the Large White-Berkshire cross—the Large White for length and the Berkshire to add fat. Very often the heavier breeds of pig have to be kept until they are baconers, and if a suitable cross is introduced, they can be passed out as porkers. The sow should only have two litters a year. In the first place, the little pigs need not be weaned so young, and they do not get such a setback. They can be weaned at eight weeks. To get three litters of pigs a year the sow must be mated three days after she farrows, but this is not advisable, because the piglets are more or less stunted, and there is a possibility of a small litter next time. The piggery should consist of a small paddock or yard with a straw stack for shelter. The pens should be placed in a corner of the yard, one pen being set aside for farrowing, with a rail 6in. high and about the same distance from the wall, to allow the young pigs to get out of the way of the sow. Put the sow into the pen several days before farrowing so that she will settle down and get her bed ready. Provide short straw. In feeding the pigs it is advisable to crush and soak the grain; pigs do better on sloppy food. There is always a certain amount of skim milk on a farm in which to soak the grain. Pigs should never be given fresh skim milk. Green hay chaff will take the place of green feed if the latter is not obtainable. It can be either soaked or scalded. A pinch of super can be added to the feed to aid the growth of the pigs." (Secretary, K. Dunn.)

July 4th.—Attendance, 14.

FALLOWING.—The following paper was read by Mr. P. Abbott:—"Fallowing is the foundation of the next year's crop, and on it depends to a great extent the success of the undertaking. The first step should be a good clean burning off, preferably during March. By that time the paddock is practically valueless as regards feed, and the resultant burn should destroy any diseased plants present in the previous crop. Fallowing should be commenced as soon as possible after seeding to conserve the early rains, and to enable the ploughing to be finished in time for the farmer to avail himself of the later rains for harrowing. During the last few years farmers have been more or less tardy as regards fallowing, arguing that late fallowing requires less

working or less strength to work it, and thus enable the cultivating to be done more quickly. These farmers overlook the fact that fallowing means the conserving of moisture for the following crop; that the early fallow benefits by the early rain, and if harrowed towards the end of August or early in September, conserves this moisture which soaks into the soil. Cultivated with a springtooth implement the finer soil is filtered to the bottom, thus making an even seed-bed. Left in this condition, little evaporation takes place during summer, and the rougher layer of soil brought to the top prevents the fallow from setting. After harvest it should be harrowed following the first suitable rain, to encourage the germination of weeds. Subsequent cultivating, if necessary, should be shallower than the spring-working. Sheep play an important part in keeping the fallow clean, and in packing the soil by constantly crossing over it."

HORSE BREEDING.—Paper read by Mr. A. Mickel:—"If people had realised what the consequences would be of nearly everybody giving up breeding horses they would have bred enough horses to maintain their teams. At the present time it is almost impossible to buy a good young draught horse. The modern type of Clydesdale is too light. If farmers had very big mares they could expect good types of horses from the new type of Clydesdale, but as only good farm sorts were available, and these mated with the modern sires, one can only expect lighter foals. In Scotland this type of horse was bred some years ago, but it was found that heavier horses had to be introduced to maintain their standard. At the present time Shire stallions are being obtained from England to improve the weight of the horses. In breeding horses, every farmer should have a few good weighty mares and then mate them with the best stallion." (Secretary, K. Dunn.)

DUDLEY.

June 6th.—Attendance, 16.

CARE OF THE FARM HORSE.—Paper read by Mr. V. Lally:—"The first requirement of the farmer who is 'starting off scratch' is a well-matched team. I prefer the Clydesdale stallion mated with a half-bred shire mare. The result is a weighty, well ribbed, active horse, with good bone and not too much hair. Some farmers at present are crossing Clydesdale mares with Percheron stallions. The result is a quiet, leggy horse, with hardly enough weight for heavy land. I prefer a stable of wood and iron, although much is to be said for a straw shed; it is cool in summer and warm in winter. It's only drawback is the danger of fire. Most farmers leave their horses loose in the shed. I prefer to have each horse in a separate stall, and all tied up. This entails a certain amount of work, namely, when tied up they have to be bedded and their stalls cleaned out daily; but it is worth the trouble. The horses are always dry, and can be cleaned down and harnessed without disturbing their feeding. Further, each horse has its own feed, and no more, as against the horse that is loose sometimes gets too much food. The main disadvantage of tying up horses is that they have to be looked after regularly. Loose horses can go in and out of the stalls, and do not want so much attention. *Feeding Horses.*—I prefer good, well-cut chaffed wheaten hay, with crushed oats, morning and dinner feeds (10lbs.), with chaff for the evening and night feeds, 1½ hours feed each. *Watering.*—Horses should be watered 1 hour after they are fed in the morning, when they are going to work, and before the dinner and evening feeds, and also last thing at night. *Harness.*—A well-fitting collar is the best means of avoiding sore shoulders; a pipe collar to fit snugly. There should be room to pass the finger between the horse's neck and the bottom of the collar. A collar that is too big can be made to fit by holding up a bran bag lengthways, putting it round and tying it up at the bottom of the horse's neck, drying the bag when wet with sweat. In working abreast teams, backbands save the horses's shoulders, taking the rise and fall of the swing, and also keep up the chains when turning around. I prefer, when possible, to work a tandem team, providing there are good leaders. The horses can be placed to better advantage than in an abreast team. *Working the Team.*—Start at sunrise, or before, if necessary; work on till about 12 o'clock; give 1½ hours for dinner; then work on till sundown. Horses that are kept working on till it is too dark to see come home wet with sweat, and they are cold and damp all night, and cannot be given a good grooming in the morning. To keep up the team's strength, every farmer should have at least one or two good mares, and breed a foal or two every year. *Mares.*—It is a good policy to always have at least one or two spare horses to always keep up the strength of the team and to provide for a sick horse. An in-foal mare should do light work up to within two weeks of foaling. The mare should be separated from the rest of the horses and kept close to home where she can be watched. See that the mare cleans and that the foal sucks and has the use of his bowels. When the foal is six months old he should be weaned. To keep the foal growing after leaving its mother, it should have plenty of good food; bran I consider one of the best feeds to keep the foal fit providing he is in good condition. He should be ready to break in at three

years old. In breaking in a young horse, first mouth him well, either by lunging him or by reins tied to a surcingle. When he can be driven on either side and leads well he should be taught to tie up. When this is done for the first time, use a branbag around the colt's neck. There is less chance of hurting his neck or of choking down; when he ties up quietly he can be put in the team, preferably on the outside in the body of a tandem team. Half a day's work is enough until his shoulders pull into shape. After a few weeks he should be able to take his place in the team." (Secretary, M. Telfer.)

GREENOCK (Average annual rainfall, 21.56in.).

June 12th.—Attendance, 38.

PAINT AND OILS.—Mr. C. Cartwright (Koolunga) read the following paper:—"Farm buildings and appliances call for several types of paint. These range from the highest grade of prepared paints to whitewash with its multifarious uses; but in purchasing paints care should be taken because there are paints for every class of material. In considering the employment of paints—particularly in reference to farmsteads—one has to naturally study the economic factors of cost and time. The farmer has a definite routine to adhere to, and painting should have its place in that routine, but if not already allowed for, a small amount of time is all that the farmer may be able to set aside for the work. When contemplating painting buildings he should note the merits of high grade paints, for it costs no more to apply than an inferior type of paint, and its life being so much longer allows more seasons to elapse before re-painting is necessary. First and foremost of the high grade paints available for this purpose there is the hardware prepared paint of lead or lead and zinc basis, colored with the necessary coloring pigments and having linseed oil as the principle constituent of the liquid portion. For roofs and tanks the paint manufacturer has prepared a range of roof and bridge paints which are lead free and are therefore essential if rain water is collected for household purposes. These roof paints are made in several different shades of red, grey, and green, and are so constructed to give the maximum durability; excessive temperature changes are experienced on roofs, and therefore the paint must possess elasticity. Of the equipment on the farm one naturally thinks of the various implements, wagons, and any machinery which is incidental to the type of farm. Whilst these are always painted when acquired they can be kept in a state of good preservation by the use of wagon or implement paints that are manufactured in several colors. Unfortunately some of the original paints on implements rapidly decays once the implement is exposed to the weather. Before applying paint, see that the surface is thoroughly clean. Paint will not harden over grease. Paint applied over a dirty surface does not stay on long, because in the hardening of paint it shrinks and causes blisters. Another type of paint which is comparatively cheap and yet efficient on mechanical parts and inside of tanks and troughs is bitumen black, which is easy to apply and can be easily recoated. Unfortunately the color limits the number of places where it might be used. A few words on oils: Boiled linseed oil should not be used unless one is aware of its actions. Raw linseed oil should be in every producer's holding because of its value for burns, drenches for stock, and the saving of tying of wheels providing they are not gone too far. If a wheel that has its spokes and tyre loose is given a good coat of linseed oil and then painted it will be years before it will require tying. A good way to oil a wheel is to get an old motor tyre, cut it in three, jack up the wheel and place part of the tyre under the wheel so that it will hold oil, fill this up with oil and allow the wheel to stand in it until it will not absorb any more oil. Then revolve it until the whole of the wheel has been completed. Let dry for a few days, then give it several coats of good carriage paint. If this plan is put into practice, instead of putting water on the wheels or letting them lie in the dam for a few hours it will save many pounds and make it much easier for the blacksmith to make a good job of tying when it becomes necessary." The following points were brought forward in the discussion:—Best colors for roof painting—green or stone colors. Patent driers were best for outside use. For iron work red oxide was thought best, with a little drying added. Kerosene should not be used in paint under any conditions. Pine tree turpentine should be used for thinning paints. Some members knew of glue having been used in paints to give a gloss. Mr. Cartwright thought it was best for an amateur to go to a professional painter to have his paints mixed. Lead-free paints were advised for ironwork, and lead or zinc paints for woodwork. Treatment of brushes after use: Wash either in turpentine, kerosene, or soap water and dip in kerosene occasionally to keep soft. To soften a brush left in paint, remove a thickness of 6 or 7 hairs from the outside, wash in extract of soap and hot water, or in boiling water. Raw linseed oil was found best to break the strength of paint. Some members found that paints remained sticky, even years after being applied. Mr. Cartwright said this was due to paint being fatty—raw linseed oil should be used to thin. Caustic soda was suitable to remove paints. Onions cut and put in a freshly painted room would take up the fumes of fresh paint. A bitumastic paint was recommended to be

used for painting inside of tanks or any damp surface. Kalsomine was considered too expensive to be used for painting outside walls. Ordinary whitewash was advised, but if desired, Mr. Cartwright said it might be colored any other color. (Secretary, A. Schubert.)

SUTHERLANDS.

Meeting held June 1st.—Attendance, 40.

VARIETIES OF WHEAT SUITABLE FOR THE DISTRICT.—The following paper was contributed by Mr. A. Twartz:—"There are some 250 distinct varieties of wheat in South Australia, but in this paper I propose to deal with early, mid-season, and late-maturing varieties. Early maturing varieties, such as Aussie, Florence, and Sultan have been tested for some years in this district. I recommend sowing the above varieties for grain: they are good yielders with plump grain, thresh out readily, and should succeed on the light land of this district. They are fairly drought resisting, and to get the best result must be sown late in the season or last of all. Sow these varieties rather thickly as they do not stool. They have a tendency to crowd out weeds. Their straw is white, and stock do well on the straw and cocky chaff. For mid-season varieties I favor Hard Federation, Rancee, and Free Gallipoli of the brown chaff varieties. These should succeed on the heavier soils in the district. They are more suited for grain than for hay, and do not grow so long in the straw. The grain being plump, it is well suited for milling purposes. Being of the brown chaff variety these are not so suited as a feed as are the white chaff varieties. They are good yielders, and easily threshed. Of the white straw varieties I recommend Caliph, Ford, Nabawa, and Felix as suitable for the district and likely to succeed in any kind of soil. These

varieties are suitable for hay or grain, have a plump grain, and good yielders, and are easily threshed, the straw and cocky chaff being suitable for stock. I recommend the straw of Felix as being suitable for thatching haystacks, &c. Of the late maturing varieties I suggest Dart's Imperial. This has white straw, and as it takes longer to mature, it should be sown at the beginning of the season. It will only succeed on the best, well-worked fallow which is absolutely free from weeds. I have had good results with this variety when sown as stated above. It is a fine milling wheat, with good flour-baking qualities. All the varieties mentioned in this paper do not shake out. For economic reasons I am not including any bearded varieties. Besides those mentioned I have also experimented with many varieties which have long since gone out of existence. I admit that many of the new varieties such as Sword are as suitable as those mentioned above, but I have not yet tried them. The varieties mentioned should be ample for the average farmer. In choosing new varieties it is important to know whether they are early, mid-season, or late maturing. Having ascertained this, the plot of land may be chosen. For the general layout of the plots I recommend 40 to 50 acres." (Secretary, E. Schiller.)

UPPER WAKEFIELD.

June 8th.—Attendance, 9.

MANAGEMENT OF DAIRY CATTLE.—Mr. J. Cleary read the following paper:—"When the calf is three days old it should be taken from the cow and fed on separator or skimmed milk; it can be brought on to the skimmed milk gradually. Sweet milk can be mixed with skimmed milk, each day making the percentage of skimmed milk greater until no sweet milk is required. In hand-feeding the greatest care has to be exercised in cleanliness. Never leave a bucket of milk in the calf yard. Remove all milk from the yard after the calf has been fed, and immediately clean the feeding vessel in readiness for the next feed. Milk will go sour more quickly than generally anticipated, and dirty vessels will bring on scours, sometimes in such a way as to be fatal. The milk should be warmed to the same heat as when taken from the cow; never use milk as it comes from the separator, it has quite a lot of gas in it, and will prove detrimental to the calf. Let the milk cool and settle from the separator, and warm it again after the froth has disappeared. Feed the calf three times a day, and not too much at a time for the first week or so—about $\frac{1}{2}$ gall. is a good meal for a young calf—the quantity can be increased as the calf gets older. After about a week the calf will commence to nibble a little grass. When it shows the tendency to feed, give about a handful of chaff and a cupful of bran. Keep a little rock salt in the feed boxes for all cattle; also feed a little sweet bone meal, this is excellent for all animals. It is most essential for the female animals, as it is a splendid preventive against 'milk fever.' If heifers and cows have a 2oz. tobacco tin full of bone-meal in the chaff about two or three times a week they will be most unlikely to contract this illness. In the case of a cow or heifer in calf, the bone-meal will assist the strengthening of the cow's internal organs, and enable her to calve without any undue loss of blood. Cows in milk should have a little bone-meal at least twice a week. Calves can be weaned off milk at about four months, but a little longer will do them good, and at the age of six to eight months in the case of Jerseys, and eight to 10 months in the case of any other breeds, the heifer can be mated. This will bring her in with her first calf at from 15 to 19 months of age. She will then be ready to commence her earning capacity for her owner, and she should be brought in with a calf once in every year, as she will do better by continuity of breeding and milking than she will if she is allowed to have much spell. Supply them with plenty of good feed, and they will milk all the time, right up to 20 years of age."

Paper read by C. F. Neumann, "THE AGRICULTURAL BUREAU."—"The Agricultural Bureau is part of the Department of Agriculture. It provides the most economic means of contact between the agriculturist and the officers of the Department of Agriculture. It is the principal channel by which the distribution of knowledge gained in research and investigational work on experimental farms and laboratories is made available to its members. In most civilised countries of the world there has been little difficulty in establishing and equipping institutions for agricultural research, but the general drawback has been to interest those concerned in agricultural pursuits. However, in South Australia there has been little difficulty in interesting the farming community because of the existence of a body of agriculturists seeking guidance on these subjects and making their information available long before the Agricultural Bureau existed. Recognising the advantages that these circumstances presented the Department of Agriculture has set itself to cultivate to the fullest this institution, which is the best means available for distributing the knowledge available to agriculturists. The Agricultural Bureau provides the Department of Agriculture with an organised centre

in every district in which there is a Branch. Thus when occasion arises it is possible to establish contact with agriculturists of a district in one body, an economical and efficient method when compared with the dissipation of time and effort involved in an individual canvass. And because of this fact it enables a small technical staff to accomplish much more than it would were there no such organisation available. Hence the various Branches of the Agricultural Bureau are looked upon as outposts in their various rural districts. It seeks the co-operation of the Branches in every possible way, in the arrangements for visits by technical officers, in the planning and conduct of experimental tests, and in the collection of data on local agricultural matters. It also encourages the local Branch of the Bureau to seek its aid on behalf of its members desiring advice on all problems affecting their crops, stock, &c. The success of our Branch lies entirely in the hands of its members. If every member gives his Branch his regular attendance and takes a keen interest in the subject under discussion there need be no fear of failure for the future. Also another factor which goes hand in hand with success is the training of our younger members, as in my opinion the Agricultural Bureau is the proper place to become familiar with public speaking, because as a rule all members are familiar with the subject and are merely asked to voice their opinions. I wish to again emphasise the above fact, because some of the younger members will no doubt be called upon later to fill the responsible positions, and on these depend entirely the future success of our Branch. There are many and various ways of exchanging ideas by means such as papers, debates, question boxes, lectures, etc., which provide many advantages to the agriculturist. The Agricultural Bureau provides a valuable medium for bringing its members together when considered from a social point of view, as by this means the members discuss many interesting and educational topics outside of the meeting. From an educational point of view the Agricultural Bureau fills a long overdue necessity in our district, as it provides an excellent medium for self-education, and takes the place of a literary society. From a general point of view the Agricultural Bureau spells success to any district, and to make the best of the many advantages offered every member of the Branch should be able at the conclusion of a meeting to say, 'I learned something to-night.' (Secretary, C. Neumann.)

WEAVERS (Average annual rainfall, 16.81in.).

May 8th.—Attendance, 9.

QUESTION BOX.—Mr. H. Cornish asked how soon after birth should lambs be tailed, and how long should the tail be left?—Mr. G. Anderson said green feed should be available for the lambs before tailing them, and the work done on a suitable day. It was advisable to leave one or two joints. Mr. Piggott said the lambs should not be driven immediately before tailing; it made the blood thin, and they were inclined to bleed excessively. Mr. G. Anderson asked: "Which is the better pickle to use for wheat or barley?"—Mr. Piggott reported very good results from formalin, turning over the grain with a shovel on the floor. Mr. W. Cornish had used bluestone and salt in equal parts and dipping the bags into the dip with satisfactory results. Mr. F. Evans spoke in favor of dry pickling. Mr. T. Farrant wanted to know a good cure for horses with severe colds. One member advised a swab of Stockholm tar, pushed down the throat, and sulphate of iron placed in the drinking water—1lb. to 1,500galls. of water. (Secretary, H. Cornish.)

June 19th.—Attendance, 13.

CARE OF THE FARM HORSE.—Mr. G. Farrant read the following paper:—"One has only to follow up the various auction sales of the season to see the enormous prices paid for good horses. In view of this fact, it behoves farmers to take better care of the horses if the maximum amount of work is to be expected from them. A horse that has received good attention and been properly handled will do a greater amount of work for a longer period than one that has been roughly treated and only half-fed. It is necessary to get a team into good condition before seeding. To do this they should be fed before commencing work. They should be fed during the slack periods of the year, if there is sufficient hay to do so. Never allow a horse to rush to water immediately after work, because they usually will drink too much; it is better to let them wait for five or ten minutes, when they will not be so hot and will drink more steadily. When about to yoke up in the morning always groom the shoulders of every horse with a good stiff brush; this will remove any dirt or sweat which, if allowed to remain on the shoulders, will encourage sore shoulders. A horse with a sore shoulder suffers a considerable amount of pain when working. It is not wise to use any preparation which will cause a hard scab to form on the sore over night. Keep the sore clean and soft over night so that a scab will not form. 'Prevention is better than cure,' and it can well be applied to the care of sore shoulders. Sore shoulders in many cases are purely the result of carelessness—working with uneven chains, or with the draught of the hames too high or too low, or illfitting collars. A horse should pull from as close to the neck as possible. A young horse should always be handled carefully when being broken in; a roughly handled animal will result in a timid and easily frightened horse. A horse will not live to do a great amount of work if it is overloaded too often. The wind becomes broken and the horse is not able to stand up to a good day's work." (Secretary, H. Cornish.)

July 3rd.—Attendance, 11.

PREPARATIONS FOR SHEARING.—The Hon. Secretary (Mr. H. Cornish) read the following paper:—"I propose to deal mainly with the small farm flocks of 500 sheep or less. The first thing to do is to get the sheep ready. Go through the flock about a fortnight before shearing, and pick out the old sheep, those of poor quality wool, and any sheep not up to standard. Raddle the culls, and if too many have been picked out the best of the rejects can be put back in the flock, and the others marked with a permanent figure brand in a conspicuous place. While this work is being done the sheep can be crutched, removing all stained and dirty wool from around the tails of the ewes and the bellies of the wethers. After shearing put another figure on the culls unless they can be disposed of in the wool before shearing time. Do not try to over-class the wool in a small clip; only pick out a few of the bad fleeces, and put these in a separate bale with the ram's wool and any odd pieces. When baling try and make all bales of uniform weight, as near 320lbs. to 350lbs. as possible, as the amount of wool available will allow. For instance, if 175 sheep cut 10lbs. of wool each do not make 4 bales of 390lbs. and one of 310lbs.; make 5 bales of 350lbs. *The Shearing Shed.*—Clean out all rubbish from the shed, and everything else that is not needed for shearing. Always aim at having a separate pen for the shorn sheep, apart from the woolies. It is very awkward for a shearer to have to drag a sheep past 5 or 6 stubborn sheep; and have the gate in the middle of the pen. Always have the wool presses up, and a bale in ready for starting. See that there is plenty of branding oil to give each sheep a clear distinct brand, and see that the brand is put on the correct place. Always try and find room for the learner in the shed, and if he does not do a good job for a start try and show him what to do."

WESTERN DISTRICT.**BUTLER.**

June 20.—Attendance, 16.

TIME OF SEEDING.—Mr. H. Turner read the following paper:—"The first week in June is quite early enough in which to make a start, providing opening rains have fallen to allow for the working back of fallow and dealing with rubbish. If opening rains are later then seeding must be delayed. Under no circumstances should seeding be done prior to the opening rains. Even new land will give better results if seeded under good conditions. Some farmers may say that owing to the area to be seeded they are unable to wait, but there is no doubt that these farmers would be better off to curtail the acreage. There are several reasons why seeding should not be started too early. Firstly—It takes 13 weeks for a grain of wheat to mature under ideal conditions, and, generally speaking, finishing conditions in this district are very good. Secondly—Wheat is subject to different diseases as soon as it is put in the ground; therefore the shortest time possible should be allowed. Thirdly—Later seeding allows better working of fallows and better germination of rubbish, and in turn gives a cleaner crop. Fourthly—Later seeding does away with rankness, and also the lodging of crops, thereby making harvesting a much better undertaking at no more risk than that attached to early seeding. Fifthly—Earlier crops cannot stand the early north winds, whereas later crops are not so much affected, and later north winds are more seasonable and not so detrimental to crops. Under local conditions I favor the sowing of mid and early wheats only, particularly the more rust-resistant varieties." (Secretary, P. R. Lange.)

CHILPUDDIE ROCK.

June 7th.—Attendance, 14.

BROOD MARES AND FOALS.—In a paper on this subject Mr. H. A. Cochrane stated that it was advisable to breed from the best mares on the farm and try to start breeding when the mares were young. It was quite safe to breed from a well-grown two-year-old mare, but the horse to which she was to be mated should not be too big, especially if she was not well grown. The best stallion in the district should always be selected. Even though it might cost a little more, it would prove to be money well spent. "Like begat like," and a good foal provided a foundation to work on when breeding later. When starting a mare breeding, she should be put to the horse early, because if she were late the first year, a year might have to be missed or she would always have a later foal. A mare's period of oestrus was about a week, with three weeks between each period, and a mare would usually get in foal more easily when going off than when coming on. If a mare proved difficult to get in foal, a good plan was to give her a douche, using bicarbonate of soda, one to two hours before service, at the rate of 4 tablespoons per $\frac{1}{2}$ gallon of warm water. A mare in foal needed every care being taken to prevent abortion. Abortion might be caused by excessive work, especially when the mare was not used to it, or to accidents, such as kicks and falls, a serious illness, or disease of the uterus. The twelfth week of pregnancy was considered a dangerous time, because the attachment of the foetus was then very weak. Contagious abortion seldom occurred with mares, but it was always wise to have mares which had aborted removed from others for a few days. In case of abortion, a mare should always be given a wash out with weak Condy's fluid. A wide swing or spreader should be used when the mare was heavy in foal. If possible, the mare should be kept out of the shafts and worked on the outside of the team. A mare should never be taken through narrow gates when coupled with other horses, because she might be bumped, neither should she be given heavy pulling. The mare should be kept in steady work until within a fortnight of foaling and then put in a small paddock—one near the home for preference—where she could be watched and given assistance if required. First it was necessary to see that the foal was presented with the head resting on the forefeet.

If that was not so the foal should be turned. When working around a mare, hands should always be disinfected and oiled. Work should be done as quickly and quietly as possible. If a mare foaled all right, she should be left alone for a time, so that she and her foal became used to each other. After a while the foal should suck the mare and have the use of its bowels. In a case of stoppage 1 eggcup full of castor oil and linseed oil should be given, also a warm enema. If the afterbirth did not come away in 10 or 12 hours it should be removed gently by hand. The mare should not mix with other horses until the foal was strong. Very few horses would hurt a young foal, but there was some danger, and it should be guarded against. If possible, the mare should not be worked when suckling a foal, but if that became necessary, the foal should not be shut up in a barb-wire yard, because it might be injured or cause the foal to become a fencer. Foals were generally quite contented if left in the yard with spare horses. Allowing the foal to suck when the mare was over-heated sometimes caused scours. A foal should be encouraged to eat as early as possible. It should be weaned at about six months. Weaning was a great trial to a foal, and he should be well provided for; if possible turned out in a paddock with green feed among other horses. If hand-feeding had to be resorted to, plenty of chaff, crushed oats, hay, and water were essential. If possible a foal should have hay as well as chaff, because it prevented him from bolting his feed and kept the teeth in order. It was a good plan to handle a foal early, which would save much inconvenience if medical attention was needed." (Hon. Secretary, H. Brown.)

ELBOW HILL (Average annual rainfall, 11in. to 12in.).

May 9th.—Attendance, 15.

HOME CONSUMPTION PRICE FOR WHEAT.—Mr. G. Payne read a paper on this subject, and in the discussion that followed, Mr. John Rehn said wheat being such an essential food should be sold at a fixed price and not a gamble price as at present. Fixing of prices had been a success in the dried fruits industry. Why not then in the wheat industry? He outlined a scheme whereby the Commonwealth Government should guarantee a fixed price of 3s. 4d. per bushel over a period of three or five years. Mr. Payne replied and said that a similar scheme had been introduced by Mr. Parker Maloney in the Federal House some time back. This scheme was rejected by the Senate. The only difference was that 4s. per bushel was the amount to be paid, instead of 3s. 4d. Mr. S. Wake said it was time farmers did something for their own benefit. They had a moral right to demand a home consumption price. All the goods the farmer had to buy were at inflated prices. Mr. Wills said a home consumption price was being favorably considered by some sections of the community. A lot would depend on the World Economic Conference. Exchange rates had much to do with the price of wheat. In England recently bread had risen by ½d. a loaf and the Government had been surprised that there had not been a big outcry against the rise. Mr. Cooper did not believe in tariffs. They were the ruination of any country and had caused a good deal of trouble in the world to-day. If other sections were entitled to bounties and bonuses the farmer was entitled to them as well. He should at least get London parity plus freight for home-consumed wheat. Mr. Story said it was not right that the amount of wheat in a 4d. loaf of bread was worth only about ½d. Mr. P. Wake said the working man was better off than the average farmer was at present. They at least did not have to work as hard or as long hours. (Secretary, W. Cooper.)

KOPPIO (Average annual rainfall, 22.40in.).

May 9th.—Attendance, 14.

BUSH FIRES.—The Hon. Secretary (Mr. M. Gardner) presented the following paper:—"Now that autumn rains have arrived and the danger from bush fires is over for another year, it is advisable to reflect on the question of preservation of fences, feed, and property for the coming year. Generally this district is bountifully blessed with a heavy growth of spring fodder, which leaves a quantity of feed that dries off and remains on the ground until it is consumed or allowed to rot away when winter rains fall the following season. The same spring growth takes place in the scrub and timber country, and with the thick bush leaves enough material to burn on suitable days. One of the most essential tasks in this district is the clearing of scrub, which is otherwise waste land, and the job of getting more scrub cleared is most commendable and necessary. Here again the onus of taking care is on the man who is thrifty and who may be classed as a worker. Scrub land is of very little use to anyone. It robs the landholder of revenue; rent, rates, and taxes have to be paid on it, and it is the policy of careful husbandry to clear land and keep it cleared. It is in keeping the land cleared that fires often get away into scrub and threaten danger. Very often when burning logs or bushes there is sufficient grass near by to run the fire away. When log fires are left burning and a high hot wind develops, the grass that would not catch alight on an ordinary day burns like tinder. It is realised that it is necessary to burn the rubbish, but it should be borne in mind that care must be

taken to see that the fire does not get away. Frequently the trouble occurs a day or two after the fire has been lighted. Hot winds blow sparks a long way and light up beyond what was thought to be sufficient break. It is necessary for someone to be on guard where logs are burning—if a wind springs up—to promptly put out the outbreaks from sparks. No matter how careful one may be there is always a risk when burning off scrub or grass if sufficient help is not handy during the job. One man to patrol the breaks and put out anything that appears dangerous may make all the difference. Likewise when fires are being controlled, there should be some men detailed to watch the wind side when others are having refreshment. There must be no cessation of watchfulness once the fire is under control till night, and then vigilance should again be maintained next morning. There have been serious losses close to this district this year through inadequate numbers of men when burning, and next burning season landholders should not hesitate to ask neighbors to assist." Discussing the paper, Mr. Low, as fire controller in the district, said it was difficult to keep control of firefighters without some uniform or distinguishing badge that was easily recognised by workers at fires. Mr. Smart thought some fixed time for burning scrub should become law because winds shifted about in the morning and became more settled in the afternoon. Mr. V. Gardner said district co-operation could well be organised for burning. As the system was at present, often several lit fires the same day and did not notify neighbors because none knew until a good day came for burning when the job was to be done. All then lit fires, and as a consequence there was not sufficient help to control them. Several serious fires had occurred not far from the district this year. What was thought apparently safe were neglected, and fires had got away.

MANGALO (Average annual rainfall, 14in. to 15in.).

May 2nd.—Attendance 11.

TRANSPORT AND THE TWO-WHEELED TRAILER.—Mr. F. Coles read the following paper:—"Because in this district transport is a branch of farming which demands the strictest economy, I offer my experience and conclusions in this regard, with particular reference to two-wheeled trailers. From a close study of the transport problem which included an exact day to day record of all journeys, reasons for such, and the loads carried in connection with my farm of 2,000 acres, I came to the conclusion that if the property was to be worked to its full producing capacity, the use of the motor vehicle was a definite necessity. Whilst making this statement, I do not mean that horses could not be used. Horses could handle the situation, but because by far the greatest need for travelling is done in trips from 60 miles upwards with heavy loads, the consequent number of animals required, together with the time involved, in actual figures works out at about the same, so that motors can be recommended for convenience. However, the records indicated that short journeys—up to 10 miles—were covered nearly always with a light load, and, therefore, promised an opening for the use of a horse-drawn vehicle. On the long trip with the motor it appeared that economy could be effected if fewer trips were run and more load carried per trip without increasing the capital outlay or renewing cost to any great extent. To serve both the short distance trip with a horse and yet permit of the same vehicle being used with motors, I built a two-wheeled cart, fitted with pneumatic tyres. This vehicle can have shafts fitted for a horse, which can be removed easily and a pole fitted so that the cart can be towed behind a car or truck as desired. The following is a description of, and a few details on the construction of the two-wheeled trailer. Two old type Ford wheels were used, fitted with roller bearings running on a stub axle cut from steel to take the wheel. A piece of 2in. piping 3ft. 6in. long serves as an axle, into this the stub axles are inserted and rivetted, over the pipe ends a collar is sweated to prevent the pipe splitting. To the axle is mounted two sets of springs, complete with scrowls, similar or the same as used on spring drays. These are clamped to the axle as near to the wheels as the body will allow. The frame of the body is built of stringybark, 2in. x 1½in., the front and rear cross members projecting 7in. each side. To their projecting ends fits an ½in. round iron stay, conveniently curved to support the sides. The floor is of ½in. Baltic flooring. The sides are of matchboard held in position by iron uprights properly spaced. The front and rear tail boards are made so that they can be lifted out. When complete, the measurements are 5ft. 6in. long, 3ft. 9in. wide, and 13in. high; from floor to ground 2ft. 3in. This, however, should be governed by the level of the draw bar on the car. From under the middle stay of the body the frame is fitted by two bolts spaced to a U bolt, at the front end is the pole. It is made from 3in. x 1½in. stringybark, and projects 1ft. 9in. out from the front of the body. Probably the most important factor contributing to the successful operating of a trailer is the device used to attach the trailer to the car. After many experiments with fittings for this purpose, I found that success and a comparatively unbreakable hitch could be made by joining the two female parts of a Ford universal joint. When these are joined, attach one end to a Ford axle, which is allowed to work parallel with the pole in two guides clamped in

preference to bolts under the pole. Behind the rear guide is a spiral spring made snug by a nut on the end of this axle. Another spring is placed in front of the front guide. These take the thrust. The universal joint is attached to the draw bar of the car by a threaded stud rivetted to the joint. This is placed through a hole in the draw bar and held fast by a large nut screwed very tightly. With a hitch of this one can operate a car in any kind of country, turn the sharpest circle, and the trailer can be put on or taken off very easily. When used behind a motor it is better to distribute any load evenly over the floor, to cope with occasions when, say, a 40-gall. drum of petrol is to be carried. Slots should be made on the sides of the body, about one-third way along, so that a piece of board can be let into them. A board in front of the drum and one behind will hold this load in the centre. After nearly two years' experience with a trailer of this description I have no hesitation in recommending every farmer to build one where the occasion demands. It is always handy, and there is no marked increase in petrol consumption in towing one. On one occasion I travelled 330 miles in 12 hours with Sewts. in the trailer behind the car. The efficiency of the outfit is now an accomplished fact." (Secretary, K. Nields.)

MILTALIE (Average annual rainfall, 13.56in.).

May 13th.—Attendance: 18.

HOME CONSUMPTION PRICE FOR WHEAT.—Mr. G. Payne read the following paper:—

"The question of a home consumption price for wheat is of great importance to every farmer in this State. It is one of the several practical ideas that can be adopted whereby all wheat producers would benefit without penalising any one section of the community to any section. Last month the Branch discussed 'How to get a better price for wheat?' and several very interesting ideas were put forward. It was stated that there were three practical methods which could be adopted: bulk handling, compulsory pooling, and home consumption price, any of which would increase the price pence per bushel. One cannot look for greatly reduced tariffs for a long time. The Federal Government's recent attitude clearly shows this; therefore, farmers must aim for something that can be put into practice with as little delay as possible. Farmers must demand at least cost of production, otherwise hundreds must go off the land very quickly. There has been a great deal said and written for and against fixing a price for home consumption. One of two things must happen—wheat prices must go up, or cost of production must come down. Producers are compelled to pay Australian price for every commodity—cornsacks, super, machinery, tools, etc. The price demanded ensures a profit to the manufacturer and a profit for everyone who handles the goods. When the farmer has wheat to sell he can only ask the wheat buyer, 'What are you giving for wheat to-day?' The farmer must take the price offering or leave it, which to-day is far below cost of production. To accept a world parity price for locally consumed wheat is an injustice and most unfair. Wherever a farmer turns he is up against organised industries; everyone but the farmer is organised to protect themselves. The flour millers have the Millers Association, which fixes the price of flour. The master bakers have an association which fixes the price of bread, and those who produce the wheat take what is offered. South Australia produced approximately 40,000,000bush. of wheat last season. The average over a period of eight years is a little over 30,000,000bush., and the home consumption about 3,000,000bush.—comparatively small to some of the eastern States. If 2s. 4d. per bushel were added to the present price, or the price give the South Australian farmer £350,000, or, roughly speaking 2½d. per bushel on a 30,000,000bush. crop. That is one of the advantages gained by fixing a price of wheat at the moment for home consumption fixed at 5s. per bushel, it would for this State alone. It may be said that the price of bread will go up, but bread should not be sold for more than 4½d. for a 2lb. loaf with wheat at 5s. a bushel. The wheat content in a 4lb. loaf is as follows:—60lbs. of wheat produces 42lbs. of flour, 7lbs. pollard, 10lbs. bran, and 1lb. of waste. In a 4lb. loaf there are about 3lbs. of flour, and it takes 4-2/7lbs. of wheat to produce 3lbs. of flour, and from that quantity of wheat, bran and pollard is also obtained. Therefore, 4-2/7lbs. of wheat is the wheat contents of a 4lb. loaf. Roughly it can be said there is a pound of wheat to 1lb. of bread. Wheat at 5s. bushel is a 1d. per lb. for bread, without considering the value of the offal. To-day bran is worth £4 17s. 6d. per ton and pollard £5 5s. There should be sufficient margin of profit for the miller and baker should bread be sold at 4d. or 4½d. per 2lb. loaf. The average consumption of bread is two loaves per week. If that is so, should any increase be made in the price it would hardly be felt. In fact, ½d. per loaf would be 4s. 4d. per year, but the benefit to the grower would be considerable. Should the price be fixed throughout the Commonwealth for home consumed wheat, the advantage to the State would be further greatly improved. Under a Commonwealth quote basis, as outlined by a proposed Federal Marketing Board, we should receive an additional £150,000, making this State's total approximately half a million, or 4½d. a bushel on a 30,000,000bush. crop—equal to last year's

wheat bounty. Recently a scheme was put forward in Western Australia, where it was proposed to establish an Australian Consumption Wheat Pool. The idea is to fix a price for home consumption wheat for the Commonwealth to return at least cost of production to the grower. This proposal has gained much favor throughout Australia. If farmers bring sufficient pressure to bear on the Government, they cannot refuse to bring in legislation to help the farmers by increasing the present price of wheat or other produce. The duties imposed on imported wheat will show what Continental countries are doing to protect their wheat industries. France has put on a duty of 3s. 6d. a bushel; 10s. 6d. on *Australian wheat*. In 1931 when wheat was 8s. 2½d. a bushel, bread was 4½d. for a 2lb. loaf. Italy has a duty of 3s. 7d. a bushel and Germany 6s. 8½d., while Sweden has a duty of 1s. 1½d. and her mills are compelled to use 80 per cent. of domestic wheat. A bushel of wheat will produce nearly 50lbs. of bread, without counting the value of offal, and yet to-day's value of a bushel of wheat will only buy seven loaves of bread. The allocation of cost of bread is very interesting. To-day wheat at Port Adelaide is on the basis of 2s. 8d. per bushel and flour is £8 2s. 6d. a ton. The latter has risen during the past month 10s. a ton. Wheat over the same period has only varied 2d. In fact, on April 1st wheat was 2s. 6½d. and flour £7 17s. 6d. It takes 48 bushels of wheat to produce 1 ton flour of 2,000lbs. and 880lbs. of offal; 2,000lbs. flour will make 1,373 loaves; 150lb. bag will make 103 loaves of 2lbs. The cost of wheat at mill door, allowing 4d. for handling charges, would be around 3s. per bushel; 48bush. at 3s. equals £7 4s., the value of offal, 880lbs., or 44bush., at 1s. 6d., equals £2 4s.; and deducting that from the net wheat cost, we find 1,373 loaves is £5, or ¾d. of a penny. Out of the above the farmer gets 2s. 4d. a bushel, freight and other charges 8d. With bread retailed at 4d. the producer receives only ½d.; the miller, baker, and others get 3½d. At the moment the price of bread is compared with the following figures:—

1920-21 season—Wheat was 9s.; flour, £18 12s. 7d.; bread, 5½d.

1930 season—Wheat was 2s. 8d.; flour, £9; bread, 5d.

To-day—Wheat is 2s. 8d.; flour, £8 2s. 7d.; bread, 4d.

Price cutting in bread is absolutely prohibited, and consumers are not getting the benefit of cheap wheat. They are paying Australian price, and the cost of bread should not increase with a fixed price for home consumption at 5s. a bushel. Should wheat remain at its present price levels, the end of hundreds of farmers is not far distant, and yet every section handling the grain is guaranteed a profit, or living wage, regardless of the low price received by the grower. In 1914 a binder could be purchased with 240bush.; to-day it costs about 800bush.; 600bush. would have bought a harvester in 1914, to-day it is doubted if 1,500bush. would buy it. The figures quoted may be of interest and represent the production of wheat for the Commonwealth over a period of eight years:—

	Bushels.
Average	140,000,000
Home consumption	32,000,000
Retained for seed and feed	18,000,000
Exported	90,000,000
South Australian production	30,000,000
Home consumption	3,000,000
New South Wales production	42,000,000
Home consumption	12,500,000
Victoria production	40,000,000
Home consumption	9,000,000
Western Australian production	27,250,000
Home consumption	2,000,000

Consumption is estimated at 5bush. per year per head of population. It would be reasonable to ask farmers to be content with London parity if this were a free trade country, but to expect farmers to supply foodstuffs under cost to workers in protected industries earning standard wages based on their cost of living, is unjust." (Secretary, G. Smith.)

June 10th.—Attendance, 9.

FARM MACHINERY.—Mr. S. Ramsey read the following paper:—"There are five essential points in the care of farm machinery—adjustments and repairs, lubrication, careful handling, protection from wind and weather, and painting. Before starting any machine, everything should be in perfect working order, and all nuts and bolts tight, especially on a binder or harvester, because there are so many important working parts. When putting in fresh bolts dip them in tar so that they can be removed without any trouble if necessary. All nuts should be tightened, especially on a new machine that has been worked for two or three days. Replace worn out parts before putting away the machine. The importance of keeping a machine ready for work cannot be over-estimated. Before starting to work any machine, lubricate all

wearing parts with good machine oil. Low cost and better work will come from machinery given proper care and attention with oil and grease. The life of an implement is often shortened by rough handling, which generally happens by hurrying over rough ground. Where a farmer has to go over a lot of new ground it is advisable to purchase a heavier implement, one especially built for rough ground. When a machine is finished work it should be housed in a waterproof shed; a machine left out in the weather is damaged by heat and rain. A lot of machinery is only worked for one month in the year and left out under a tree for the remaining 11 months. In that case more damage is done to the machine when it is standing idle than for the month it is in use. A machine neglected in this way soon has a second-hand appearance. It is possible to get long service from an implement only when it has proper shelter when not in use. All machinery should have a coat of paint occasionally, it adds a few years life to the wooden parts of machinery and also improves the appearance. Neglect of machinery has meant the ruin of many a farmer." (Secretary, G. Smith.)

PYGERY.

May 9th.—Attendance, 9.

PESTS AND THEIR DESTRUCTION.—Paper read by Mr. R. Woodrup:—"This paper is intended to deal with animal and bird pests which from time to time harass the farmer, and methods employed to destroy same. Rabbits are the chief offenders. The occurrence of rabbit plagues coincides with the return of good seasons, or seasons of abundant feed following droughts. Droughts check the numbers of the pest, owing, no doubt, to the scarcity of feed and water, but with the return of seasons of abundant feed the rabbit, being a prolific breeder, very soon assumes plague proportions. There are many methods used to destroy this pest. Phosphorous poisons, used per medium of the poison cart, being most generally used in this district. This method is fairly efficient if properly used. The laying of this poison with the poison cart gives best results if used immediately following a rain during any of the summer months, and before any green feed appears. Where there are large burrows, and the poison cart is being used, the users usually go right around the burrows with the cart; a better method is to more or less follow the runs that go out from the burrows and often radiate in various directions. When phosphorus is being mixed, it should not be touched by hand, but in a receptacle where it can be effectively mixed with a stick. If the pollard is too sticky, the addition of wheat meal or bran will make it of a consistency that will readily cut with the knife of the machine. When conditions are not good for the use of the poison cart, and the ground is wet—as in the winter or spring months—fair results can be obtained by using cynogas, a chemical preparation which, when exposed to air, gives off deadly fumes. This chemical is used by being laid in or pumped into burrows, which are then blocked up to prevent escape of the fumes, the latter, being heavier than air, penetrates to all reaches of the burrow. The results from this method are sometimes made negligible by the action of outside rabbits which open the burrow from the outside. Other methods used are suffocating with carbon monoxide. In this method a car, truck, or tractor is employed, the exhaust gases being carried through rubber hose into the burrows, all exits of which are filled with earth. Strychnine poisons are very effective, especially in summer, but many people object to the use of such owing to the possible danger to stock, through chewing bones, &c. Foxes can also rightly be described as pests, and, unless some effort to keep them in check is adopted, they take considerable toll of young lambs. A common practice of destroying foxes is by laying baits poisoned with strychnine. Some people claim that small baits of poisoned caul fat are the most effective. Good results can be obtained with poisoned baits of fresh liver from freshly killed sheep; these should be laid at intervals along a trail made by dragging sheep offal or a freshly killed fowl opened up. Care should be taken that the baits to be laid are not touched by hand. Liver can be opened up with a sharp knife, while held with a stick with the other hand. A suitable place to lay baits in summer is around and some distance away from a water trough or dam, where they are accustomed to come for drink. Eagle hawks, too, are a feathered pest that can do a deal of damage among young lambs. They also seem to have a liking for fowls. They are wily birds, and are difficult to shoot. These destructive birds can be caught by making a cylindrical wire netting cage, 15in. or 18in. in diameter, and placing therein a young white fowl. This should be taken out in the paddock and placed on the ground and anchored. Then a number of rabbit traps should be set close together all around the caged fowl. If these eagles are about they will very soon sight the fowl, and in their endeavors to get at it they will almost surely get in the traps, which, if possible, should all be linked together by a thin wire. It often happens that these birds go in pairs in search of food, and if one happens to get alongside an expected feed it is soon joined by its mate, and the chances of both getting in the traps are good." (Secretary, A. Day.)

ROBERTS AND VERRAN.

May 17th.—Attendance, 5.

CARE AND TRAINING OF A SHEEP DOG.—Mr. S. Barber read the following paper:—"In choosing a puppy, see that you select one from a litter of pure-bred sheep dogs. While puppies from a cattle and sheep dog cross make useful dogs, they are usually too timid for cattle and too rough for sheep. In selecting a pup from a litter, let the mother do it by putting the puppies out in a row and away from the nest, and it will be noted that the mother takes the best pup back to its place first. This should be done three times in succession to make sure of the right pup. If no confidence is placed in this method, the observance of the following points may be helpful:—See that the pup has a pointed head—this denotes intelligence; see that the roof of the mouth is black—this denotes hardiness. Always select a bitch, for they are best workers and most intelligent. *Care of Pup.*—After taking the pup from its mother, see that it gets plenty of milk, and feed it on cooked meat, which has been cooked in water to which salt has been added. This keeps worms away, thereby giving the pup a better chance to thrive. Keep the pup in a good, warm kennel and teach it to tie up, but do not keep it continually on the chain, because this makes it too eager to chase anything about when it grows to the age when it is to be trained to work. *Training of Dog.*—Start as young as possible, and a lot of patience will be needed. The dog will make mistakes, but do not lose your temper and illtreat it. If the latter is done, the dog becomes frightened and loses confidence; very often a good dog is spoiled in this way. Kindness and coaxing will give very much better results. A good way to start a young dog to work is to take it out with an old dog and couple them together; it then soon becomes accustomed to the other dog's ways and understands more readily. The owner of the dog should do the training, as he always uses the same method of working the dog, either call, sign, or whistle. Under no circumstances should anyone else be allowed to handle the dog until it is thoroughly broken in, and only then with a full explanation of how the dog works." (Secretary, C. Masters.)

PREPARING PIGS FOR MARKET.—Mr. Coombs read the following paper:—"When getting pigs ready for market they should be confined in a sty—not more than three pigs in the one enclosure. The type of sty recommended as a run of, say, four or five in a straight line. Pitch pave with limestone and cement the joints. Make the sties 10ft. x 12ft. In this district, where there is a shortage of big timber and plenty of stone, I recommend that the walls be built of stone and plastered with cement. For the roof, broom bush makes a very good covering, it is warm in winter and cooler in

summer." Mr. Coombe here used a blackboard to demonstrate the type of sty that he advocated. "The sty has a cleaning race down the back of the buildings. This can also be used for loading or unloading pigs. It is necessary to have the ramp at the top end of the race. With the small sties the pigs do much better when they cannot ramble about. Further, for best results, the pigs must be kept clean and dry in winter. Have a good supply of clean water in summer. The roof can be put over the whole of the sties fairly high above them to allow plenty of room for light and ventilation." (Secretary, H. Elliot.)

RAMCO.

PRUNING.—The following points are taken from an address by Mr. F. Elliott of Waukerie, who used pieces from various trees and vines and a pair of secateurs to illustrate his remarks. There were different ways of pruning trees and vines, said Mr. Elliott, not only in the actual operation, but also with regard to life and financial results. The great factor required was judgment. A vigorous vine should be given something to do, but if the vine was weak then its work should be reduced. Trees and vines differed, and it was not possible to make a set standard. His remarks on pear pruning were illustrated with a lateral cut from a main arm which was cut to a fruit twig. It had two wood shoots. He advised cutting one out and allowing the other to go. It would not go far, but fruit back and build up. Apricots.—Laterals should not be cut too hard, they would grow again. The laterals could be left until they spurred, then built up with judgment. It was better to leave alone rather than treat drastically. The limbs must be protected from sun in hot climates or they would burn. If a leader was growing strongly and was cut back it would only go ahead again. He advised leaving it alone—it would not go far and could then be dealt with. He favored rubbing off, in early spring, growth that was not wanted. If that was not done then he would not cut the resultant laterals, but about December they could be bent over. Treatment for peaches was similar to the above. They should be pruned according to the sap channel. Vines.—Again the speaker stressed the importance of judgment of the individual vine. Before pruning the Sultana the vine should be examined and the growth compared with last year's treatment. If vigorous then one more cane than last year could be left; if weaker one cane would be removed, leaving about the same number of rods. Cuts should be made at the correct angle; the square cut gives a less exposed face. Cuts should not be made too close to buds. (Secretary, J. Odgers.)

SOUTH AND HILLS DISTRICT

CLARENDON (Average annual rainfall, 33.91in.).

April 24th.—Attendance, 11.

FARM ECONOMY.—Mr. H. Harper contributed the following paper:—"There is much truth in the old proverb, 'a pound saved is a pound gained.' The better treatment that is given to the stock on the farm the better return they will give, whether it be horses, cows, pigs, or sheep. The same principle can be applied to the farm orchard or garden. **Implements.**—Too often they are left standing in the sun and rain, and in this district where the rainfall is about 32ins. one season's exposure to the weather

will do more harm than the work they do in two years. Build a shed, even if only of timber and straw, and it will keep off the sun and most of the rain. House the implements in the shed when not in use. If fences and gates are allowed to become dilapidated it takes pounds off the value of the property. I prefer gates to slip-rails; the latter are often out of repair and take much time to open and shut. Gates are cheap to make and are much quicker to open and safer when shut. From three or four shillings' worth of timber, a few bolts or nails, a gate can easily be made that will last a number of years. Good hinges can be made out of parts of old machinery. If this kind of gate is too much expense a good makeshift can be made with three iron droppers. Stretch four wires across and a piece of netting, put a piece of chain and a spring hook on one end, and it will act more satisfactorily than rails. Fences are another important factor. If allowed to get out of repair young stock soon acquire the habit of creeping and become a curse for ever after. By putting in a cuddler or two where the posts are broken off, the fence may last for a number of years. By going around the fence once a year with the strainer and tightening up the broken and slack wires, much improvement can be made. With regard to tools, 'a place for everything and everything in its place' will save much time and annoyance. It often takes longer to find the tools than it does to do the job.' (Secretary, T. B. Brooks.)

FINNISS.

June 5th.—Attendance, 7.

USES OF CONCRETE.—Mr. L. Dunn read the following paper:—"With a concrete feeding floor in the sties, a farmer knows that the pigs can get all he gives to them and that they will not trample the feed into the ground. If the floor is constructed with a kerb around it, the feed will be doubly protected, because the pig will not be able to nose the food off the feeding surface. The concrete used for this work consists of one paper bag of cement to 2 cubic ft. of sand and 3 of broken stone or gravel. The particles of broken stone or gravel should not exceed 1½ in. in diameter. *Mixing.*—Mix the cement, sand, and gravel thoroughly, so that the combination will have a uniform color. Then mix in sufficient water to secure a workable concrete. Do not add too much water. In order to prevent the pigs from slipping on the floor, finish the surface off with a wooden float, which will give a gritty surface. Too much trowelling should be avoided. Care should be taken to see that the floor is thoroughly 'cured' before being used. The floors of the sleeping quarters should also be con-

ALSO MANUFACTURED—

Blood Manure

Bone Manure

creted. I recommend that a wooden covering be constructed, which must be movable so that it can be removed and the floor underneath cleaned out. *Pig Wallows.*—On farms that are situated away from creeks and waterholes, concrete wallows should be constructed for the use of pigs in summer. A wallow 20ft. long and 12ft. wide, sloping from 9in. to 15in. deep, will accommodate 20 pigs. The bottom should be sloped so that the wallow can be cleaned out when necessary. The concrete in this wallow consists of 1 part cement, 2 parts sand, and 3 parts gravel. *Concrete Fence Posts.*—Fence posts that will neither rot nor burn put an end to periodic replacement expenses. The farmer can make these posts between seasons. A rectangular mould 6ft. in length, with a cross section of 4ins. or 5ins. at the base, tapering to 3ins. or 4ins. at the top, can be built with smooth straight-grained timber. A good plan is to place wet brown paper inside the moulds—paper cement bags being ideal for the purpose. The wet paper prevents the concrete sticking to the mould. Other good ideas are to paint the insides of the moulds with crude oil, linseed oil thinned with kerosene, or machine oil. Quarter-inch steel bars running the length of the post are used as reinforcing; in rectangular posts, a rod is placed in each corner 3ins. from the two adjacent sides. The mixture used for post consists of 1 part cement, 2 parts sand, and 3 parts screenings or gravel, the screening or gravel not to exceed ½in. in diameter. When the mixture is placed in the mould it should be well worked around the inside of the mould to ensure a smooth surface. If the posts are made in summer, they can be removed from the mould in 24 hours; in winter a longer time is required for the concrete to harden. Do not use posts as soon as taken out of the moulds; "cure" them in wet sand for several days. *Durable Walks in the Farm Yard.*—Most paths should be constructed of 4ins. of concrete. A good plan when constructing paths is to divide the path into sections and to put down each alternate section. When the paths are put down in this way it prevents cracking, but see that each section is dry before the remaining sections are put down. After the concrete has been placed in the forms it can be levelled off with a straightedge. To secure a gritty surface, finish the work with a wood float. To "cure" the concrete, place wet bags over it for about a week. Where the path is being continually used, the mixture should consist of 1 part cement, 2 of sand, and 3 of gravel." (Secretary, L. A. Dunn.)

INMAN VALLEY (Average annual rainfall, 26in. to 27in.).

June 15th.—Attendance, 12.

SCRUB FARMING.—The following paper was read by Mr. D. Nosworthy:—"The scrub land in this district can be divided into three classes:—First, the hilly type, with rather heavy timber and large yaccas. This particular kind is only suitable for grazing; therefore, clearing for the plough is too expensive. Knock the hearts out of the yaccas in winter, starting in May, and grub on until October. As soon as possible, ring the trees that are considered too big for falling. The smaller ones can be chopped close to the ground. The chopping of the small trees would make enough room to get through with the top-dressing machine. All the axe work should be completed by the end of December on account of the need for the leaves and bark to fall to carry a good fire over what has been cleared. This is very important, and, if possible, pick a day when a hot north wind is blowing, after which very little work will be necessary before the ground is ready for clover or other seeds. The method of seeding depends entirely on the thickness of the yaccas. If possible, a drill will make the best seed bed for clover seed, but if the conditions are not good enough, then a broadcaster will do the job very well. It will take from 3 to 5 years for the yaccas to decay. Then top-dressing annually will do all that is required to make this sort of land some of the best in the district. Any shoots from either either trees or yaccas must be knocked off before the growth becomes too strong. It is an excellent plan to keep a good flock of 3 or 4-year-old wethers in the paddock; they will kill both kinds of shoots. On no account should the young growth be neglected. May or June is the best time for this work, because the sap is dormant. Twice over the shoots will prove sufficient to kill 90 per cent. of them. A mistake often made is that more scrub has been knocked down than can be looked after; this should be avoided. There is a large area of scrub that consists of low stringy bark and very small yaccas. This is best handled with a roller or log. This class of country is being very successfully handled by Mr. J. B. Roberts, of Mount Compass. Fallow this land, and then sow with oats and clover seed early the following year. On scrub of this sort the shoots persist longer than on the heavily timbered country, but experience has proved that ploughing 2 or 3 years later will almost rid the land of stumps. The best treatment for white sandy land covered with bracken fern is to leave it in its natural state. It cannot be expected to bring green scrub land under full profit for at least 6 to 8 years. (Secretary, H. Lewis.)

LENSWOOD AND FOREST RANGE (Average annual rainfall, 35in. to 36in.).

May 29th.—Attendance, 9.

Mr. E. Leishman (District Instructor) presented a Life Membership certificate of the Agricultural Bureau to Mr. H. Schultz. Addressing the meeting on South Australia's export trade in apples, Mr. Leishman in the course of his remarks said:—“While Australia held her own amongst her competitors there was great and urgent need for uniformity, both in quality and package. South Australia had made definite improvement in the last few years in both directions, but whereas softwood cases were used exclusively in this State, other States were using different boxes of different woods, some of which were unsuited for apple packages, and all were called ‘Australian apples’ when they arrived at their destination. Packing and standards also differed even within this State, but he thought the time would come when these difficulties would be greatly minimised. Of the two methods of transport—rail and motor truck—motors were the worst offenders at bruising fruit. They were stacked too high and the bottom layer—when projected too far over the side rail—must unavoidably be bruised because it had the rest of the load bearing upon it in one spot. A very marked improvement was noticeable in the handling the fruit received at the wharves. Ships crews also showed a desire to handle fruit as well as possible, one firm using timber to place between the boxes to provide ventilation, which when unloaded had to be thrown away. This timber, which was ultimately wasted, was worth £2,000. In a number of instances printed labels which curled and peeled off gave cases a bad appearance. Brands also placed on haphazardly, and sometimes upside down, also told against good appearance. With regard to quality, light or medium crops should be avoided when picking, and large sized apples should not be exported. Sizing of fruit was not all that it should be. Grading and packing he thought should be two separate jobs. Fruit sold by count was more sought after by overseas buyers, because they could better estimate their supplies. Twenty-eight varieties of apples were shipped last year, which was far too many. Corrugated straw-board was thought to be the best packing-case lining. Labels with a white back ground showed up best and looked most attractive. Wiring must be done near to the cleat. Its object was not to tighten the case around loosely packed contents, but to protect the case from pilferage, and its object was best achieved by being close up to the cleat. Packing must not be done on a flat table. Bottom bulge must be made while packing, and not created by being put on the press and pushed through.

He suggested that a Board of Control should be set up in the United Kingdom to prevent rough handling and control the sales. At present, according to reports, a great deal of the care taken this end was nullified by the rough handling it received upon arrival. (Secretary, B. Lawrance.)

SHOAL BAY.

July 4th.—Attendance, 38.

The evening was devoted to a lecture by Mr. Lines, of the Animal Nutrition Research Institute, on experimental work conducted on Messrs. Seager Bros.' property at Hawk's Nest. He gave an outline of the experiments and results in connection with coast disease. After the address the experiences of those present were given, many of which Mr. Lines considered of value. (Secretary, E. B. Bell, Wisanger.)

STRATHALBYN (Average annual rainfall, 19.34in.).

May 10th.

The following papers were read by boys of the local high school:—

THE CODLIN MOTH (P. Bidstrup).—"The codlin moth is one of the worst pests that the fruitgrower has to deal with. It causes a considerable loss for that particular year, although it does not damage the tree for further crops. The codlin moth causes worm eaten or maggoty fruit of apples chiefly, although pears, plums, quinces, peaches, and apricots fall to its ravages. The moth is of a greyish color, but sometimes it is tinged with brown. It appears soon after the blossoms fall, and lays its eggs upon any part of the tree, but generally upon the fruit. The same moth never deposits two eggs in the same apple. The grub hatches from 8 to 10 days, and obtains its first few meals from anywhere on the apple. At this stage the grub is open to attack by means of sprays, which have been put on the apple before the grub hatches. For this purpose a poisonous spray is necessary, arsenate of lead, mixed with flour or glue to make it stick, is perhaps one of the best. Two and a half gallons of arsenate of lead to 50galls. of water for the first spraying, and 1½galls. of arsenate of lead to 50galls. of water for subsequent sprayings, give the best results. The spray should be applied with a fine nozzle, and an attempt should be made to cover all the apples with a thin layer. It is absolutely essential that it should be put on at the right time. This time is when the petals have just fallen, and the spray then enters the calyx cup before it closes, which it does some 10 days after the petals have fallen. If this is done the grub is generally poisoned as it is beginning to bore its way into the apple, for the main point of attack is at the eye of the fruit. Two more sprayings of the same ingredients should be given at about 4 to 6 weeks, and 10 weeks after the fall of petals. The object of these is to kill any later hatching of grubs. If the grub is not killed at this stage it is impossible to stop the destruction of the fruit, for once it is inside the apple it is quite safe and the damage is done. The grub generally burrows into the core, thus causing the fruit to drop prematurely. If the grub is fully developed before the fruit drops it eats a fresh channel out and lowers itself to the ground by means of a silken thread. If it has not left before it falls it does so then, and straight away seeks shelter. At this stage the grub is again open to attack, although a thorough wiping out cannot be given, for there are many places in which the grub seeks shelter. Rubbish, old bags, straw, posts, but chiefly loose bark form a hiding place. By securing a piece of hessian about 6in. wide around the trunk of the trees, a suitable hiding place is made, and many moths can be lured into a trap by this means. The hessian should be removed at least once a week, and all grubs killed. Fowls allowed to feed in the orchard eat many of the grubs. The grubs that secure a safe hiding place spin themselves a cocoon, so mixed with pieces of surrounding material that it forms a substantial shelter. In this the grub changes into a chrysalis. The chrysalis may develop into a moth in 7 to 10 days, or later. If it is the last brood for the season the grub does not change straight away into a chrysalis, but remains hidden until a few weeks before the flowers burst, and then changes, coming forth as a moth soon after. When the moths are observed, it is possible to kill a few by means of traps, consisting of a tin containing a sticky substance, such as apple juice mixed with honey being hung up in the trees. This method is sometimes successful, but more frequently only a very few are captured. The moths soon mate, and before long lay about 80 eggs. Sometimes the eggs are infertile, due to cold, foggy weather or to the moths failing to mate, generally the latter under Australian conditions, as infertility is rare. The life cycle generally begins again with a great increase in numbers."

THE PREPARATION OF LAND FOR WHEAT (G. Yelland).—"Preparation of the land is of vital importance in the growing of wheat. It is more important than manuring, seed treatment, &c., all put together, especially in drier districts, where water conservation is the object. The usual rule is to precede wheat with a fallow. Results show that fallow crops practically double the returns of stubble. The following are some figures to illustrate:—In 1926 stubble crops averaged 8bush. in Australia and fallow crops

averaged 14bush. In the following two years fallow crops averaged about three times as much as stubble. So it generally pays in the long run to fallow, although it means two years' rent. Land for wheat requires an early stirring, followed by frequent cultivation to conserve moisture, and to make a good consolidated seedbed, easily penetrable by roots. There should be a 1in. to 2in. loose mulch on top. These conditions may be attained by long periods of fallow (10 to 15 months). In drier districts the soil must be broken up finer to conserve moisture, but in wetter districts the main thing is to kill weeds. The land could first be ploughed about 4in. to 5in. deep as soon as possible after seeding, and then followed by a packer or harrows. It can then be cultivated to the full depth of ploughing. After this keep down weeds, preferably by grazing, and conserve moisture by cultivating after every fall of rain over, say, ½in. in heavier districts, and over 30 points in lighter soils, bringing each successive cultivation shallower, leaving the loose mulch on top. Bare fallow is now quite common in South Australian wheatgrowing. The following figures show the progress made:—In 1900, 34 per cent. of wheat grown on fallow; 1910, 50 per cent.; and 1926, 66 per cent. On a wheat farm in New South Wales over a 2-year period, stubble crops gave 11bush. average, and fallow crops 21bush. The following are the figures obtained:—The 21bush. gave a gross return of 84s., from which the deduction of 65s. working expenses leaves 19s. profit per acre; the 11bush. on unfallowed land realised 44s., and cost 50s. to produce, showing a loss of 6s. per acre. This was a typical wheat belt. Unfallowed land may carry 2in. to 3in. available moisture, and fallowed land will conserve an extra 3in. to 5in. So in dry districts fallow is extremely important. Then comes the order or cycle in which to grow wheat. If fallow and wheat are grown alternately without a period of rest or pasture, the organic matter in the soil will slowly deteriorate. The organic matter in the soil is the most important soil constituent. Wheat cannot be grown continuously on the same land. It will soon be grown at a loss. It has been proved, however, that wheat can be grown continuously on new land and also on older land by heavy applications of manure and 28in. to 30in. rainfall. Nowadays sheep are generally run in connection with wheat farming. To keep sheep continuously, a rotation must be worked so that some paddocks may be grazing and others in wheat. Also different crops take different proportions of the soil constituents; if two wheat crops were grown in succession phosphates and nitrogen in particular would be used. If wheat had taken all the disease should be followed by oats, which are immune from it to starve it out. Different districts again require different rotations. The following are some typical rotations:—(1) Fallow-wheat gives good returns for a period of years, but is very exhausting to the soil. Only suitable on rich, black friable soils. (2) Fallow-wheat-pasture; this gives a little less return but maintains humus and nitrogen supply and helps keep land clean. (3) Fallow-wheat-oats or barley-pasture or fodder crop (peas) return more humus, and peas supply nitrogen. Oats starve out take-all and flag-smut. Suitable for districts over 16in., and most suitable for this district. (4) Fallow-wheat-fallow-oats-pasture has most of the advantages of No. 3, but is better suited in drier districts, under 15in. (5) Peas-wheat-barley-oats—only in cases 22in. to 28in. rainfall, where fallow is unnecessary. (6) Fallow-wheat-peas-wheat-oats-grazing for 18in. to 22in. It gives 4 revenue crops in cycles. But wheat is not always preceded by fallow. A stubble wheat crop should follow other crops, whose cultivation more or less prepares the land for wheat. This will only occur in 22in. to 30in. rainfall. A stubble wheat crop following another serial could be treated as follows:—Burn or graze the stubble, plough early as possible, then give a short period of preparatory cultivation. The seed will then be sown on a loose seedbed."

CONSERVE YOUR ESTATE.

35, CURRIE STREET ————— ADELAIDE.

TREATMENT OF YOUNG TREES BEFORE PLANTING (L. Oakley and L. Thring).—"The trees should be obtained from a reliable nurseryman. The tree may be headed, which means cut back in the nursery, but sometimes it is not headed. The roots are most likely fractured and they will be growing in all directions. If possible obtain a guarantee that the tree is free from disease. If the tree has no guarantee it should be dipped in bordeaux mixture or kerosene emulsion. The bordeaux mixture is made up of 8lbs. bluestone, 4lbs. of lime, and 25galls. of water. This mixture should be only used for dormant trees. The kerosene emulsion consists of 2galls. kerosene and 1lb. soap mixed with water. This dipping will kill living fungus diseases or disease spores which may enter the plant through the cut section of roots or stems. On planting the tree, make sure that the stocks are suitable to the soil. If the tree is a straight stick when it comes from the nursery it should be pruned back to a bud, about 9in. to 1ft. high. If the tree is headed in the nursery the branches should be pruned back until only a few inches from the main stem. When pruning the stem back to a bud make sure that the lowest part of the section is above the bud, otherwise the sap will evaporate out of the low part and the bud will die. The section should be made by a pair of secateurs. The tree may be knocked about and the main roots may have broken ends, and may be growing upward instead of down or across. The broken ends must be cut off to make clean cut sections; cut out the roots which are growing upwards. The object of cutting off is to allow the cut to heal quickly to lessen the probability of the tree getting diseased before it heals. Do not remove the top until the tree is in the ground. When this treatment has been effected it is ready to plant. A black mark will indicate its depth in the nursery, so when planting the tree make sure it is put in to the same depth again."

C. Griffin gave a short description of the care and uses of carpentry tools. (Secretary, F. Allison.)

FARM STOCK AILMENTS AND REMEDIES.

Paper read by Mr. W. F. Roads at a recent meeting of the Inman Valley Branch.

THE HORSE.—One of the most common troubles the horse is subject to is flatulent colic. Some people are apt to think that the horse has water trouble when colic is prevalent, but this is very rare with horses at any time. The three chief causes of colic are:—(1) Overwork when out of condition; (2) errors in diet; (3) worm trouble. Many farmers who should know better put horses fresh from the paddock into hard work; the horse is soft and his muscles flabby, and in a couple of hours he is exhausted, and if not released from work is very likely to go down in the team or as soon as taken out. This is a stomach pain brought on through exhaustion. The preventive for this is not to work the horse too heavily for a few days, and feed good food for a few days in advance.

Error in Diet.—It is bad practice to give a horse a feed of chaff and put him straight to work on a full stomach should he be running on green feed. If it so happens that this cannot be avoided, put a pint of bran in the chaff and that will help to keep the horse's stomach moving. Another horse will go down in the night after a day's work, even though he be in good working order. This horse usually comes home hungry and bolts the feed. The remedy for this is to feed a sheaf of hay until his appetite is relieved, and then give chaff. Any horse that has shown a tendency to colic should always be watered before meals.

Worm trouble is the worst offender for pain in the stomach. The worms take all the goodness out of the blood vessels on the walls of the paunch and cause severe digestive disorders. The worms attack horses of all ages, although they may be quite fat and even with good coats. The blood worm is so small as to be hardly visible to the naked eye. **Remedy.**—Starve for 15 hours and give a drench of 1½ pints linseed oil and 2 egg-cups of turpentine, and repeat in three weeks. If you have reason to suspect sand as a cause of trouble drench with milk and honey. A simple remedy for wheat gorge is bicarbonate of soda every two hours until relieved, with an enema of soapy warm water, and as much water as the animal will drink.

Cattle are somewhat different from horses in their manner of eating, &c., and they are not so subject to stomach pains as horses. If a cow scours badly for any length of time, it can be attributed to digestive troubles. Too much bran, too much clover hay or early green feed will upset the best cow, and the remedy is to balance it with food not so rich, such as chaff or good cereal hay or some other roughage. Another complaint not generally understood is mineral deficiency. Cows on heavy, top dressed country seldom show it, but the best cure is sweet sterilised bonemeal in the feed—a tablespoonful twice a day. This also acts as a general tonic, both for dry bible and milk fever.

Milk fever seems to be on the increase and it must be recognised quickly and prompt action taken. The first precaution is to ascertain that the cow's bowels are working well; if not, drench carefully while she still has her senses and power to swallow. A bottle of linseed oil and 2ozs. of turpentine with a little ground ginger will prove

helpful. Be sure and bed the cow down well and keep her warm and propped up on her brisket. Wash the teats and udder with disinfectant and keep a clean sack under her bag. Sterilise hands and instruments. Use a milk fever outfit in preference to a bicycle pump and inflate the udder tightly. Tie the teats with tape if necessary, and if one application is not successful repeat again in two hours.

Cows that frequently return to the bull should be syringed with a quart of warm water with Condyl's crystals, diluted to a wine color, for a couple of weeks before coming in season. This should be done carefully once a day until a few days before, and then an hour or so before service inject a quart of lukewarm bicarb soda. If it is evident that a cow will have a difficult calving, give her 12 hours' trial by careful watching; if by that time she is still in trouble assistance may be needed, such as putting the calf in a better position or using force by hand. Should the cow not clean quickly, a scalded bran mash is a good and simple remedy.

Mammitis.—The simple form of this trouble is caused through a bruise, a knock, or a congested udder after calving. This kind generally rights itself after massaging with camphor oil, following a quarter of an hour's fomenting with flannels rung out in hot water. Infectious mammitis is practically incurable and very dangerous to the rest of the herd. Even if cured, it leaves weakened quarters, with more or less caloused lumps around the base of the teats, which makes milking difficult. Such cows should be sent to the butcher.

Lumpy jaw is caused mainly through an infected tooth. The jaw gradually develops a hard lump, and eventually the jaw breaks. The tooth cannot be pulled because the jaw would be so weakened that it would break in two. The veterinary surgeons effect a cure by putting the beast under chloroform and boring a hole underneath the tooth. The tooth is then punched out with a hammer and the cavity filled with a disinfectant on cotton wool.

Impaction often claims a beast in death, and this usually shows up about mid-winter. It is caused through cattle eating dry, indigestible grass and herbage in the previous summer and autumn. Cut plenty of meadow hay and feed in these months, and there will be little trouble in this respect. The cure is to give a strong purgative and then a little later administer 3galls. of warm soapsuds as an injection.

Pigs are not subject to many ills other than digestive disorders. Give them green feed and plenty of charcoal to eat, and not much trouble will occur. Bloat in cattle or pigs can be relieved with linseed oil and turpentine as a drench. The danger with bloat in pigs is off green pastures and milk fresh from the separator. If the pigs are on grass, always arrange to have the previous milk for feeding. In case of bloat in cows, place a stick in the mouth in the form of a bit, and this with a smearing of Stockholm will generally effect a cure in 15 minutes. Cows subject to bloat should not be allowed in luxuriant pastures unless they have had a morning feed of solid food of hay or chaff. Scours in calves are nearly always caused through overfeeding or unclean feeding utensils. Keep clean buckets for feeding, give about a quarter of the milk that the calf would drink normally, and add about 1 quart of whole milk, after which there will be a gradual improvement. A good plan is to first give 1 tablespoonful of castor oil.

WOMEN'S BRANCHES.

WOMEN'S INTERESTS IN COUNTRY LIFE.

[By Mrs. CARNE, Penola Women's.]

(Paper read at the 44th Congress of the Agricultural Bureau, September, 1933.)

The life of the average country woman who has her home and its welfare at heart is a very busy one, nevertheless life under Australian conditions is much more fortunate than any other country, for there is a freedom of open spaces like no other country in the world.

To make that country life profitable is not altogether such an easy matter, and it needs the help of every woman to curtail any undue expenditure and create that little profit whereby country life becomes more comfortable.

Life on the land is full of inconveniences, not like city homes, built to regulations, with all labor-saving devices; indeed, one has only to read that recently published book by Mrs. White entitled *No Roads Go By* to realise the hardships some women endure in the far north of Central Australia, which fill us with admiration, who with their cheerfulness and determination seem to overcome all obstacles.

Life for men on the land is none the less trying, for the prices of products to be profitable are hard earned during these days of depression.

Much diversified opinion has been given lately by men and women in letters to the press as to whether a woman should help her husband in outside work. Much depends upon the stamina of the woman and the work in progress, whilst no doubt her man appreciates the help nevertheless she must remember upon her health and strength depends the welfare of the home, and if in later life the heavy work, such as lifting, &c., may possibly undermine the health, resulting in endless medical expenses, then it has not been worth while.

A home that is worth while, no matter how humble, if it be spotless, its children healthy and clean, its larder well filled, and the health and strength of the parents unimpaired is a home.

Recently a writer to one of the daily papers mentioned that "a man on the land needs a lawyer and a private secretary to cope with the various correspondence received." Very often this is one of the many little things that a woman can do to help. Many men detest the business side of farm life, and if a woman takes a keen interest in balancing the budget of her household expenses, then she is certainly a capable person to handle the correspondence received in that household.

All households should be "run" on an allowance, and whether the necessary items be paid or entered it is a small matter to wait for the docket and check all expenses, keeping the paid and unpaid accounts upon two separate files. Each month's accounts should be reviewed by every housewife in a small cash book kept for the purpose of receipts and expenditure, leaving "the man of the house" or head of the household the books for farm expenditure, merely showing allowance. This does away with pages of household commodities in case he has to engage a lawyer to furnish his income tax.

POULTRY.

The management and marketing of poultry can also be run by women. This is often an interesting hobby. From experience I find the White Leghorn more of a pest than any other fowl unless cross-breeding is adopted. Whilst without doubt they are the best layers if housed and cared for they are, when allowed their freedom, into all places least expected. Being of a restless nature they do endless damage to haystacks and gardens, lay their eggs in unthought-of places, and if disturbed shift sometimes further afield. Of course, if eggs are the main point in view, White Leghorns can be housed and cared for, but this entails much

work. The cockerels are useless for marketing—never gaining much condition—and if any great distance from the city the freight takes the profit. The black or grey fowls are more suitable for table use and marketing, and are good layers until they reach their second year.

Turkeys, if the time can be spared, are more profitable, but are difficult to raise. I have raised a large number of turkeys annually. As soon as a clutch is hatched, I place the mother (turkey hen or fowl) in sections of an old disused tank out on a grass patch with wire-netting over the top to prevent the bird from flying out as a turkey hen is very clumsy. Give clean water daily, and a warm mash of pollard or table scraps, or crushed wheat mixed with pollard three times daily.

Drag the tank section to a fresh patch each morning, because turkeys are grass-loving birds. The sides of the tank protect the delicate chicks from keen winds, and if the weather is wet a few sheets of plain or corrugated iron held firmly down by weights of wood, planks, &c., keeps them dry and warm. I have no faith in rearing turkeys loose; they either get lost or die with cold, or the gobblers kill them. I wonder at Nature making the turkey hen such a stupid mother!

MARKETING.

In the marketing of poultry do not overcrowd the birds, and nail the tins to the insides of boxes; it is cruelty leaving them without food and water when the tins capsize.

If birds are to be consigned by rail fill the food tins with wheat or oats before they leave the home, and give instructions for water to be added at the station whilst awaiting the truck.

In the marketing of eggs let them be clean and fresh even though the price is most disheartening, but as in all farm produce let us hope for better times ahead.

MENDING AND RUG MAKING.

During winter when the housework is completed and out of doors is only of sheer necessity, there is always that everlasting mending or patching where children are concerned, and I have found it worth while in the mending of tweeds and serges to hunt up a scrap of material of which it was made and unravel it. Mending the torn edges with its own material, even sometimes if the effort looks a little clumsy, a vast difference is made when pressed with a damp cloth.

There is always knitting and sewing to do, but it is remarkable in these times of depression what hobbies some of our country women have undertaken. Many are the beautiful hand-made rugs that one sees in these homes made from scraps of waste material on clean hessian foundations or on canvas. Some are works of art in design.

Those worked in skeins of wool in harmonising colors on canvas are more expensive—costing from 21s. to 35s. Others again are made of unravelled woollens, hooked through the desired material in lockstitch, and when completed being clipped short and level with a sharp pair of shears. I have seen rugs of clipped sheep skins trimmed well, and either home tanned by an advertised preparation or sent to a tanner. Many people like black as a color for floor rugs, but it is a hard color to keep clean.

JAM RECIPES.

It is during winter that very often the supply of jam in the pantry runs low—perhaps we underestimated the consumption—so whilst oranges are in season we can help the pantry with a little marmalade, for which a well-tested recipe is as follows:—

Marmalade.—Two large oranges and 2 large lemons. Cut the fruit very fine, removing all the white pith from the skins, and using the skins also. Measure cut up fruit, and allow 3 cups of cold water to each cup of fruit, and stand aside

until about the same time next day; then put on the fire, and boil hard for 10 minutes. Then lift off and set aside until same time next day. Then add 1 cup sugar to each cup of pulp and $\frac{1}{2}$ cup of sugar over, and then boil till it jellies (about an hour).

Dried Apricot and Pineapple Jam.—1lb. dried apricotes, 2qts. water, 4lbs. sugar, 1 cut up pineapple. Cover apricots with boiling water in which 1 teaspoon soda has been added. Soak $\frac{1}{2}$ an hour. Pour off water, then add 2qts. cold water. Stand 24 hours. Bring to boil, adding pineapple and sugar.

Jam Pudding.—Beat 1 tablespoon sugar, 1 tablespoon butter, 2 tablespoons dark jam, $\frac{1}{2}$ cup milk in which 1 teaspoon carbonate of soda is dissolved, and add pinch of salt and 1 cup flour. Steam 2 hours. Sufficient for five or six persons.

GARDENING AND HOUSEHOLD WORK.

As spring advances we are tempted more and more out of doors, and work among the household vegetables is combined with pleasure when reaping the reward of one's labors. The raising and planting of "shelter" trees is also an interesting hobby, and the majority of country women can dig the necessary holes for these quite as well as any man. The Cootamundra Wattle and the Tree Lucerne are easily raised, grow rapidly, and make ideal shelter from winds.

In spring cleaning of the household, if worked in a methodical manner of one room at a time, it will be more pleasant to the household.

In most homes a different room in the house has its "thorough" cleaning weekly, yet it is surprising how dirty some of them are found to be when spring cleaning. It is not "turning out" a room properly if the furniture is not moved from against the walls and the skirting boards left unwashed.

When the wallpaper is only slightly soiled it can be freshened by rubbing over lightly with stale bread, or a ball of dough if very dirty, working with an "up and down" movement. If the paper is damaged or torn, and some of the original covering is available, it is not a difficult matter to patch it, whilst carefully noting the pattern, pressing firmly into position.

The woodwork of furniture should be carefully washed with warm water to remove dust from the crevices, adding a little vinegar, and when thoroughly dry polished with a wax polish. Stained boards can be re-stained or waxed. Walls can be patterned or plain, but as a general rule if the furnishings are patterned it is better to choose plain walls; or, if the carpets and coverings are plain, then a patterned or "roughened" surface is often more suitable.

All blacklead brushes should be boiled in an old tin with a small quantity of soap and soda every now and again, and hung out to dry.

To preserve wire mattresses from rusting rub them over with a soft rag saturated in paraffin oil; if they persist in rusting, give a coat of aluminium paint.

If all mattresses have an extra cover—these can be made at home or bought ready made—it will save a lot of trouble in washing and re-filling. I often think these few lines by Longfellow are aptly fitting:—

"Labor with what zeal we will,
Something still remains undone;
Something uncompleted still,
Waits the rising of the sun."

SWEET MAKING.

[By Mrs. B. EGGERS, Wasleys Women's.]

(*Paper read at the 44th Congress of the Agricultural Bureau, September, 1933.*)

When making sweets, one of the most important rules is to weigh all materials carefully. Use only the finest sugar. Always cover the sugar and other ingredients with water, unless otherwise stated in recipe. Too little water will cause a batch to

burn, and a little extra will only take a little longer to boil out. This, of course, cannot be done when the batch is being timed by the clock, but then the exact quantity of water is given in the recipe. Always boil sweets fiercely. A primus is very handy where gas and electricity are not procurable. When the ingredients have been put into a saucepan and put on the stove stir until the batch starts to simmer or until the sugar dissolves. Wash the sides of the saucepan with a brush. I use a round pastry brush, dipped in warm water. This is to prevent any grains of sugar staying on the sides of the saucepan. Do not allow the brush to touch the batch, but a little water running into it will not hurt it. Do not stir the batch, unless otherwise stated in the recipe, after it comes to the boil. This is a very important rule if one wants a fine candy or a clear toffee. When using a thermometer be careful not to allow it to become higher than the degree stated in the recipe. Always remember that no matter how much the ingredients may be increased or decreased the degree for boiling still remains the same. Always warm the thermometer before placing it in the batch. Glucose is used in most recipes to prevent granulation. Cream of tartar may be substituted, but when making chocolate centres the use of glucose produces a much finer and softer article. There is more likelihood of the batch burning when using glucose, so for toffees, butterscotch, or any other high degree sweet I use cream of tartar. A wooden paddle is used for stirring the batch before it boils and again if it is necessary to beat the mixture after it comes off the stove, being careful, of course, to wash it before using the second time. A two-pronged fork is used for dipping chocolates and bon bons. When using glucose always dip the hands in water, then pull out as much as is needed. If one has to put their hand in for more, dip again in cold water. Weigh the sugar, and then weigh the glucose on top of it. This prevents the glucose sticking to the scales. Always use sheet gelatine, and after soaking it until soft, dry it on a cloth before using.

RECIPES.

Toffee.—3lbs. sugar, 1 teaspoon of cream of tartar; cover the batch with water, and stir until sugar is dissolved. Wash the sides of saucepan, and boil to 315°, or until, when tested in cold water, it will immediately become brittle, like an egg shell. Flavoring and coloring may be added, if desired, when the batch is ready. By putting it in just as the saucepan comes off the fire the mixture, still boiling, will send the flavoring through it. Pour into a buttered dish. If nuts or preserved fruit be used, place same on the bottom of the dish, and pour the mixture in carefully in order that the nuts are not disturbed. Just before it is cold mark the top with a sharp knife the size required, and, when cold, take out of the tin, and it will break off quite easily. Another way is to cut the batch with buttered scissors, when just cool enough to handle, into pieces, and form with buttered fingers the shapes desired. Yet another way is to cut in strips and then crossways.

Butterscotch.—Same amount of sugar and cream of tartar, but boiled to 320°. Take off the fire, and when it has ceased to boil add ½lb. butter. Beat until well mixed, but if beaten too much it will go sugary. Turn out into greased tin or dish, and cut the same way as toffee.

Milk Kisses.—2½lbs. of sugar, 4½ teaspoons cream of tartar. Moisten and boil to 270°, or, until tested in cold water, it becomes crisp and will break, but not as hard as for toffee. Boil this sweet very fiercely. Take off the fire, and add ½lb. butter and ½ tin of condensed milk. Malt or honey may be used instead of milk. Beat this in, and pour into a greased tin. When cold, cut or break off, and wrap in wax paper.

Cocoanut Ice.—Take 1½lbs. sugar, ½lb. glucose; moisten and boil to 235° or, when tested in water, it becomes a soft ball between the fingers. Take off the fire, and divide in two. Beat up one half, and, when getting white, add ¼lb. cocoanut; pour into a cigar box lined with wax paper. Beat up the other half and color pink, and add a little essence. I do not add cocoanut to this half. Pour on top of white.

Chocolate Ice is made the same way, but when beating up second half add a little melted chocolate instead of pink coloring.

Jujubes.—Take 15ozs. sugar, $\frac{1}{2}$ teaspoon cream of tartar, 2ozs. gelatine. Place sugar and cream of tartar in saucepan, moisten with water, and boil to 240° or soft ball degree. Take off the fire and add the soaked gelatine, color and flavor, and return to the fire, stirring for 1 minute. Pour into a tin moistened with water, not buttered. When set cut up and roll in ordinary crystal sugar.

Caramels.—This is one of the few recipes that is stirred all the time. Place 1lb. sugar in a saucepan with 12ozs. glucose and 1 cup of sweet cream. Stir to 245° or between the soft ball and the firm ball degree; then add $\frac{1}{2}$ cup more cream and boil to 245°; add another $\frac{1}{2}$ cup of cream and boil again to same degree. Remove from the fire, flavor with a little vanilla, and pour into a greased tin or dish. I use sandwich cake tins. When not quite cold mark with knife, and when cold cut into squares. Do not use too large a cup for the cream, or the batch will be too soft.

Chocolate Caramels.—Add $\frac{1}{2}$ lb. grated chocolates to the mixture; nuts may be added after it comes off the fire. Wrap in wax paper.

Fondant is the base for chocolate creams. To make: Take 1 $\frac{1}{2}$ lbs. sugar and $\frac{1}{2}$ lb. glucose; cover with water and boil to 240°, or soft ball degree; pour into a basin and when getting white from beating, add stiffly beaten white of one egg. Do not start to beat until mixture is luke-warm. Take small quantities and flavor with whatever is desired and work into shape with the fingers, using cornflour to prevent sticking. Some may be left white and flavored with either lemon or vanilla, and made pyramid shape; others colored pink and flavored strawberry or raspberry; others vanilla flavored, with a little butter worked in; coffee essence may be added to some, and a little caramel to darken. Raisins, nuts, and crystallised fruit may be used by flavoring some fondant vanilla and wrapping a piece around each nut or piece of fruit.

Peppermint Creams may be made by using a little peppermint essence in some fondant. When the centres have been formed, place them on wax paper to allow the outsides to get firm. Next day they are ready to dip into melted chocolate. Scrape any quantity of block chocolate into a double boiler. I use one small basin placed in another larger one. Have warm water in the under basin. Stir the chocolate in the small basin until it has melted, keeping the water in the under basin no more than very warm. If too much heat is used it will cook the chocolate which will become coarse and hard. If it is too thick add a little scraped cocoa-butter. The less heat used in melting the chocolate the less danger of a grey and spotted coating. When cocoa-butter is used care must be taken to have it well mixed into the melted chocolate, otherwise it may streak. It sometimes takes hours to melt the chocolate sufficiently. Beat it well all the while, keeping scraped well away from sides of basin. To test take out a little and place on wax paper. If hard and glossy in 5 minutes it is ready for dipping; if it takes longer stir a little more. When it is ready, drop in the centres one at a time, and before they have time to melt remove them with the fork; scrape off the superfluous chocolate on the side of the basin, and place on wax paper to dry.

Toffee, butterscotch, cocoanut ice, caramels, jubes, or any such sweets may be used as chocolate centres. A very nice chocolate is vanilla fondant wrapped around an almond coated with chocolate, and a raisin placed on top, also *vice versa*. Preserved ginger cut in small pieces and mixed with fondant makes another nice centre. Peanut clusters may be made by melting chocolate as directed, then dropping peanuts in and take them out 5 or 6 at a time. Chocolate roughs, by melting chocolate and adding cocoanut; place in rugged lumps on wax paper.

Licorice Allsorts.—Place 1lb. sugar, 1 $\frac{1}{2}$ teaspoons cream of tartar in a saucepan, moisten and boil to soft ball degree. Take off the fire and add $\frac{1}{2}$ oz. soaked gelatine. Thicken in the saucepan with about 2lbs. icing sugar. Sift some icing sugar into

a dish and pour the boiling mixture into the centre and work into a thick paste. Roll out $\frac{1}{4}$ in. thick and place a piece of thin licorice on top, roll out another piece of the mixture and place on top of licorice. Cut with a sharp knife.

Puff Balls.—Soak 1 oz. gelatine in 1 cup water for 2 hours. Add 1 lb. sugar and 1 cup water and boil about 10 minutes. When cool beat until stiff. Turn into moulds, either egg cups or small marmite pots. Wet the moulds before putting in the mixture. A gem scone tray is another good mould. When set, dip in melted chocolate and roll in cocoanut. The moulds may be dusted with corn-flour instead of being moistened.

Honey Comb.—1 lb. sugar and a good pinch of cream of tartar, moisten with water and boil to 320° or egg shell degree. Take off the fire and stir in a small teaspoon of butter and a large teaspoon of carb. soda. Stir ingredients as little as possible, and quickly. Pour into a buttered tin and when cold cut with buttered scissors.

THE FUTURE WOMEN OF AUSTRALIA.

[Mrs. F. CUMMINGS, Belalie Women's.]

(Paper read at the 44th Congress of the Agricultural Bureau, September, 1933.)

Mrs. Edison, wife of the great inventor, in an article entitled "The Biggest Job in the World," writes:—"I am old-fashioned enough to believe in the old saying that the hand that rocks the cradle rules the world." I agree with Mrs. Edison in that, but how many mothers realise this and the big responsibility which is theirs? The baby girls of to-day will be the future women of Australia, and the mothers of the generation to come. How careful then should their training be; for the women will have much to do towards making Australia the land for which our pioneer parents worked and hoped.

The training of our little women cannot begin too early; quite a young child can be trained in the habits of neatness and carefulness. The small task of taking care of the toys and putting them carefully away will instil in the child habits which will be useful in later years. Give the little ones simple duties to perform, which they will do willingly to "help mother." This may not be a help, as oft times the work has to be done over again; but do not discourage the small helper, because she is early learning the sense of responsibility. Teach them to see the beauties in Nature; flowers and music are all aids in forming beautiful characters.

SCHOOL DAYS.

Too soon our girls commence their school days, and other interests enter into their lives. Most mothers dread this time and the influence of perhaps unsuitable companions, but keep your girls' confidence, and help them to choose their friends wisely. I have heard mothers say, "Oh! I never listen to tales brought from school," but I do not agree with them in this respect. Listen to the little stories of things which vex or worry during school hours, then advise or explain their faults. It is not necessary to side with the child if it is in the wrong, nor to encourage what is known as tale-bearing. In this way you keep your child's confidence, and also know how she spends her play hours among her school mates.

Invite the school mates to your home, and learn to know the friends your daughter has chosen. Girls should be given every opportunity of mixing freely and playing with children of their own age.

The girls should understand that it is their duty to make the best use of school hours, and that education is one of the best assets for a successful life. No child should waste these valuable years, but do not allow the growing girl to over study. Nothing undermines the strength and makes nervy, irritable girls

more than the strain of too much study. A mother of a family once said to me, "I never sacrifice my children's health for their education." Education after all is worthless without good health.

HOME TRAINING.

The young girl should be taught how to spend wisely, and the best way to do this is to make a small allowance for pocket money. One of the greatest of wrongs can be done to the child by giving too much pocket money. This is not unusual just now as money is too scarce with most parents, but many of the extravagant habits and ideas of so many young women are due to the fact that in their childhood days they were given an unlimited supply of pocket money to spend as they pleased.

It is a good idea to let the pocket money be earned by some small daily or weekly task. On the farm it can be easily arranged that the girls care for the poultry or help with the cows, and money earned in this way will be more valued. They soon learn to spend their money wisely; if spent foolishly they are the losers, and will know better next time. We all learn by experience, but often for lack of proper teaching in our young days experience is gained in a hard school. Keep the girls at school as long as you can; they are the happiest days of their lives, and soon enough they will have to shoulder the cares of life. Besides when a girl leaves school, say, at 14, she grows into womanhood far too quickly.

It is a pathetic sight to see these young girls—in dress and manner—copying girls many years their senior with the innocence and bloom of childhood gone for ever.

School days ended our girls have to take up bigger responsibilities either in the home or at business, but unless your young daughter has been taught to be useful do not expect her to settle down quietly to the responsibility of work of any kind. The life will be new and irksome to her. For instance, the little girl who has been allowed to help mother on baking days, or to try her hand at stitching up a frock on the sewing machine will feel confident when she takes up the work in earnest. If mothers get away sometimes for a holiday, and leave the young housekeeper to manage without running to mother for advice it will help her to become capable and independent.

Where there are two or more daughters let them take week about at cooking and housekeeping, and so become competent in all the things which help to make a house a home.

Why do so many of our girls go to towns to work in offices and shops instead of qualifying for what Mrs. Edison calls the "biggest job in the world"—home making. Mothers should not be pushed into the background, but girls should realise that she comes first.

Do not let the girls form the habit of thinking anything will do for mother who never needs a new dress or a holiday. In one sense it is not fair to mother who sacrifices so much for her children, and in another it will make a selfish woman of the daughter, who will grow up to think only of herself. Every girl should have a dress allowance, be it ever so small.

Girls enjoy spending their own money for clothes; they then realise the value of money, learn to spend wisely, and dress well. Every girl should be brought up to take a pride in her personal appearance. It does not, as some people think, cause vanity in children to foster a love for pretty clothes, for a tidy, neat, and well-dressed woman is certainly preferable to a slovenly and careless one. Do not let the girls run accounts for drapery; if they cannot pay for what they want it must not be bought. Teach them Mr. Micawber's maxim, "Spend 19s. 6d. out of your pound and you have happiness, but spend 20s. 6d. and you have misery." How many people would be saved a world of trouble at the present time if that advice had been acted upon! Extravagance has ruined many homes in late years.

Girls should be taught to respect the aged and have reverence for the higher things of life, for noble and pure-minded women are needed in the world to-day.

RECREATION AND AMUSEMENTS.

On a recent visit to the city my husband and I visited one of the theatres just to pass away the evening. The play was a disappointment to us, and to my mind very low classed, but every suggestive story or vulgar song was greeted with great applause by the audience, which consisted mostly of young girls and their boy friends, showing the depraved tastes of a great number of the young folk of to-day. Are amusements of that kind—which I believe are common enough in the city—going to do anything to form the noble women we want to carry on Australia in the future?

An interest in things outside the home circle is necessary, as sooner or later the younger generation must step into the positions filled by their elders. To this end it is advisable to encourage the girls to take an interest in social work, such as social clubs, guilds, &c. It is selfish to live for oneself alone, and an interest in the outside world will give broader views of life.

In the matter of sport and amusement much may be said. I do not believe in "all work and no play," and neither do I favor "all play and no work." Sport is a fine thing for girls in moderation, and helps to instil in them many valuable lessons which go to make character. Taking a defeat good naturedly—at tennis, for instance—will help them to make the best of the setbacks which are sure to come some time in life.

The tendency of late years has been to place too much value on sport. It has been overdone, and had our young folk of late years put as much time and thought into their "jobs" as they have their sport the country would be better off to-day. A well-known minister recently made this remark, "Pleasure and sport is not an end, but a means to an end. To make it one's sole interest in life is wrong, but in moderation it is a great help in character building." So let your girls have amusements—their sport, dances, and social entertainments—but as a recreation only, not their chief aim in life. If you like your young girls to attend public dances—and personally I see no harm in this class of amusement—go with them and know what company they are in. Get to know their young companions, and show them that they are free to entertain their friends in their own home. It is not always a pleasure to accompany young girls in the evenings, an easy chair by the fire with work or book is more enticing, but mothers are often called upon to make a sacrifice for their children.

Cultivate in your daughters a taste for good books; one who is fond of reading is rarely discontented or bored with home life. Mothers should not be discouraged with their job of training the young; we all have our disappointments, and one cannot expect perfect results, but you will have the satisfaction of knowing that you are doing your part towards raising a generation of pure-minded, industrious women in whom we must trust to help our beloved Australia and make it a good and great land.

I conclude by quoting a few lines from a poem which I learnt many years ago:—

"The girls that are wanted are good girls—

Good from the heart to the lips—

Pure as the lily is white and pure,

From its heart to its sweet leaf tips.

"The girls that are wanted are home girls—

Girls who are mother's right hand—

That fathers and brothers may trust in,

And the little ones understand."

MILLICENT (Average annual rainfall, 29.77in.).

June 16th.—Attendance, 13.

STEWES, CURRIES, AND WINTER PUDDINGS.—The following recipes were submitted:—*Orange Dumplings* (Mrs. J. Schultz).—Mix 3 cups bread crumbs with $\frac{1}{2}$ cup each castor sugar and S.R. flour, $\frac{1}{2}$ cup soft butter, and grated rind of orange. Moisten with a well-beaten egg, juice of an orange, $\frac{1}{2}$ cup of milk. Put into small buttered mould, cover, and steam 20 minutes. Serve with orange sauce or hot marmalade. *Date Pudding* (Mrs. R. Oberlander).—2 $\frac{1}{2}$ cups flour, 1 cup suet, $\frac{1}{2}$ cup sugar, $\frac{1}{2}$ lb. dates, 1 cup milk, $\frac{1}{2}$ nutmeg, 1 teaspoon soda. Boil 3 hours in a basin. *Seven Cup Pudding*.—1 cup each of bread crumbs, flour, chopped suet, sugar, currants, $\frac{1}{2}$ cup milk, 1 egg, 1 teaspoon of cinnamon, 1 teaspoon c. soda. Mix all dry ingredients together, beat the egg, and add milk. Stir both into dry ingredients, mixing well. Put into a greased basin, steam for 2 hours, and serve with a sweet sauce. *Suet Pudding* (Mrs. Nitschke).—2 cups flour, 1 cup shredded suet, 1 teaspoon soda, 2 teaspoons c. tartar. Mix with milk, put into a floured cloth, and boil 1 $\frac{1}{2}$ hours. To be eaten with treacle or honey. If desired, 1 cup each of sugar and raisins can be added, and the pudding eaten with hot milk or cream or sweet sauce. *Mutton Hot Pot*.—Take 2lbs. lean mutton, cut into neat pieces. Fry in butter until brown. Have a saucepan half full of water boiling when the meat is ready. Put into the saucepan. Have ready 1 carrot, 1 parsnip, and 1 onion to put in the frying pan. Fry until brown, then add to meat in saucepan. Boil for 1 hour, then add thickening. Place in a casserole, put in the oven, and bake another hour. Mutton treated in this way is delicious. *Boiled Jam Rolly* (Mrs. Altschwager).—To make the pastry take $\frac{1}{2}$ lb. flour, pinch of salt, $\frac{1}{2}$ teaspoon baking powder, $\frac{1}{2}$ lb. suet, $\frac{1}{2}$ cup water. Sift flour and baking powder, shred suet, and rub into flour. Add water to make a soft dough. Roll out the crust, spread jam over, moisten edges, roll up, and press edges together to prevent jam from coming out. Tie up in a floured cloth, fold over, leaving plenty of room for the pudding to swell. Tie the ends securely, and put a pin in the middle of the cloth. Have the water boiling when the pudding is put in. Boil 1 $\frac{1}{2}$ hours. *Jam Rolly, Baked*.—Paste: 1 cup flour, 1 tablespoon butter, 1 teaspoon baking powder, pinch of salt, mixed with a little milk. Roll out, and spread over with jam. Roll up, and put in a buttered dish. Pour over a syrup made of 1 cup water, $\frac{1}{2}$ cup sugar, 1 tablespoon butter (boiled), and bake 30 minutes. *Plum Pudding Without Eggs* (Mrs. L. Oberlander).—6ozs. each flour, suet, bread crumbs, raisins, and currants, 2ozs. each candied peel and brown sugar, 1 teaspoon spice, $\frac{1}{2}$ teaspoon carb. soda, $\frac{1}{2}$ cup treacle, 1 cup milk. Shred suet, rub it into sifted flour, salt and soda, add crumbs, then add cleaned fruits. Cut up peel, then sugar and spice. Blend the treacle with the milk, stir all in, and mix well. Boil either in floured cloth or in a greased pudding basin, with cloth tied on top, or in a greased pudding mould with self-fitting lid for 4 hours. Serve with white sauce. *Sago Date Pudding*.—1 cup each bread crumbs and dates, $\frac{1}{2}$ cup sugar, 2 tablespoons sago soaked in cup of milk for 1 hour, 1 teaspoon carb. soda in a little milk, 2 tablespoons melted butter. Mix all ingredients, butter last. Steam in a greased mould 26 hours. Serve with a powdered custard sauce. *College Pudding* (Mrs. H. J. Hutchesson).—2 cups S.R. flour, 2 eggs, 1 tablespoon butter, $\frac{1}{2}$ cup milk and water, 2 cups sugar. Beat eggs for 20 minutes. Dissolve butter and sugar together, add to eggs with milk and water, and then sift flour in slowly and stir in. Put a little jam in basin, and pour in ingredients. Steam for 1 $\frac{1}{2}$ hours. *Apple Dumplings*.—2 cups flour, 2 teaspoons baking powder and pinch salt sifted together, add 1 cup chopped suet. Make into soft dough with milk. Flour the hands, take a piece of dough, and bury the peeled apple well. Put into a deep, well-buttered piedish, and on top of all sprinkle a cup of brown sugar. Then pour over them 1 cup boiling water. Bake $\frac{1}{2}$ to 1 hour, according to oven, and serve with cream. This quantity makes 6 or 7 good sized dumplings. *Cottage Pie* (Mrs. Bryant).—Mince 1lb. steak kidney, and 2 onions together, add pepper and salt to taste. Mix altogether with a small cup of soup, and place in a buttered piedish. Have a sufficient quantity of mashed potatoes to spread on top, adding little pieces of butter. Bake for 1 hour, according to heat of oven. *Seasoning Salts*.—Home cooks will find it a great advantage to prepare salts, especially for seasoning, and keep on hand for flavoring soup, &c. Take 6ozs. salt, $\frac{1}{2}$ oz. ground cloves, 1oz. ground ginger, $\frac{1}{2}$ oz. each cinnamon, cayenne, nutmeg, black pepper, and Jamaica pepper. Mix all together well, place in a bottle, and cork tightly. Add a little to the soup. (Secretary, Mrs. M. Hutchesson.)

MUNDALLA (Average annual attendance, 19.22in.).

June 8th.—Attendance, 14.

QUESTION BOX.—The meeting took the form of a Question Box. A member who asked the best way to test the heat of an oven was advised to place a newspaper or flour on the oven slide and if same browned quickly, the oven was well heated. As a preventive for

dandruff in the hair, the following were suggested:—(1) Use colinated cocoanut oil; (2) rub salted water well into roots of hair with finger tips; (3) one part kerosene and two parts olive oil rubbed well into scalp. Mrs. Hawke addressed the meeting on "Girl Guiding."

July 6th.—Attendance, 15.

HOUSEHOLD HINTS.—Make children's flannelette underwear fireproof by this simple precaution: After washing dip the garments into a solution of alum water; this renders the material non-inflammable. Put salt between two layers of paper at the bottom of cake tin and cake will keep fresh for some time. To keep moths away, instead of placing moth balls or camphor among woollen goods, sprinkle oil of cinnamon on small pieces of cotton wool and place among clothes. If the washing copper is dirty after becoming hot rub well with a kerosene rag and all will be well and the kerosene will not harm the clothes. This recipe of Monte Carlo biscuits was given by Mrs. L. Fisher by special request, and the secretary can thoroughly recommend same as she tested them at Mrs. Fisher's home:—

Monte Carlo Biscuits (Mrs. L. Fisher).—1lb. plain flour, 3ozs. sugar, $\frac{1}{2}$ lb. butter, 2 tablespoons water. **Method**—Rub butter and sugar well together with fingers, mix in water, and shake flour in gradually. Rub all together, roll out on floured board to biscuit thickness, cut into shapes (I use a $\frac{1}{2}$ lb. mustard tin) and mark with the back of a fork. Bake in a quick oven until light brown. **Filling**—Make a paste of the following mixture: $\frac{1}{2}$ lb. icing sugar, 2 tablespoons butter, $\frac{1}{2}$ to 1 teaspoon of vanilla or pineapple essence. When biscuits are cold, spread generously with paste and lightly press another biscuit on top. These biscuits will keep a long time in airtight tin. (Secretary, Miss M. Kemp.)

SADDLEWORTH (Average annual rainfall, 19.54in.).

July 4th.—Attendance, 12.

BISCUIT RECIPES.—The following recipes were supplied.—**Ammonia Biscuits.**—1 pt. milk, $\frac{1}{2}$ lb. butter, 1lb. sugar, 1oz. ammonia, and flour enough to roll. **Honey Biscuits.**—6 eggs, $1\frac{1}{2}$ lbs. sugar, 1lb. lukewarm honey, 2 teaspoons each cinnamon, ginger, cloves, and carbonate soda, 2 $\frac{1}{2}$ lbs. flour. **Cream Biscuits.**—1 cup each cream and sugar, 2 eggs, 1 teaspoon c. tartar, $\frac{1}{2}$ teaspoon carb. soda, enough flour to stiffen. **Iced Currant Biscuits.**— $\frac{1}{2}$ lb. butter, 2ozs. sugar, $\frac{1}{2}$ lb. flour, 2 level tablespoons baking powder, 1 egg, 2 tablespoons milk, 2-4ozs. currants, salt. Sift flour and rising. Rub in butter, add sugar and currants, mix egg yolk and milk together and stir into flour. Roll out thin on floured baking dish. Beat the egg white and stir in 4ozs. sifted icing sugar gradually. Spread thinly over the surface of biscuit, make in finger lengths, and bake in moderate oven about 20 minutes. **Munchies.**—2 cups rolled oats, 1 cup each sugar and cocoanut, $\frac{1}{2}$ cup flour, $\frac{1}{2}$ cup butter, 2 large tablespoons honey, 1 teaspoon carb. soda, 1 tablespoon hot water (boiling). Mix dry ingredients; melt butter and add honey. Dissolve soda in boiling water, add to dough. Drop on slide; bake about 10 minutes in slow oven. **Honey Biscuits.**—1lb. sugar, $1\frac{1}{2}$ lbs. honey, 4 eggs, 4 teaspoons carb. soda, 2 teaspoons mixed spice, $\frac{1}{2}$ nutmeg. Flour enough to roll out, essence of lemon and a little ginger. This mixture makes a large quantity. **Walnut Rice or Puffed Rice Biscuits.**—Cream 6ozs. each butter and sugar, 1 beaten egg, $1\frac{1}{2}$ cups each S.R. flour and puffed rice, 1 tablespoon chopped walnuts, flavor essence of almonds. Roll into small balls, put on cold slide, and bake in moderate oven 10-15 minutes. **Biscuits.**—Pinch of salt, 2 cups S.R. flour, $\frac{1}{2}$ cup sugar, $\frac{1}{2}$ cup butter, egg. Mix dry ingredients, then make into a stiff paste with yolk of egg and a little lk, roll very thin. Beat the white of egg to a stiff froth and add icing sugar to form an icing; spread on dough. Sprinkle with cocoanut, cut in fingers. Cook in hot oven 15 minutes. **Flaked Oat Biscuits.**—6ozs. flaked oats, 4ozs. each sugar and butter, vanilla. Mix with melted butter, bake in dish, and cut into squares when cooling. **Size of dish 10ins. by 7ins.** **Sunday Biscuits.**—3 cups flour, 3 tablespoons cornflour, 3 teaspoons each cocoanut, c. tartar, $1\frac{1}{2}$ teaspoons c. soda. Beat $1\frac{1}{2}$ cups sugar and 3 tablespoons butter to a cream, add 2 eggs and 2 tablespoons milk. Mix with flour, etc., to a stiff paste. Bake 12 to 15 minutes in moderate oven. **Cornflake Biscuits.**—2 whites egg, 1 cup sugar, 1 teaspoon vanilla, 3 cups cornflakes, $\frac{1}{2}$ cup cocoanut, $\frac{1}{2}$ cup chopped almonds or walnuts, 3ozs. butter. **Method**—Beat egg whites, add sugar, vanilla, cornflakes, cocoanut, and almonds. Melt butter, and pour over mixture; mix in lightly. Put 1 teaspoon on slide and bake in cool oven. **Easy-meal Biscuits.**—4ozs. each plain flour and butter, 2ozs. sugar, 1oz. easy-meal. **Method**—Cream butter and sugar, add easy-meal, then flour. Roll out thinly and cut to required shape. Bake in medium oven. **Jam Drops.**— $\frac{1}{2}$ cup sugar, 2 cups flour, $\frac{1}{2}$ cup butter, 2 teaspoons baking powder, 2 eggs. Beat butter and sugar to cream, add eggs, then flour. Make into stiff balls, press a hole in the middle and fill with jam. Bake in a quick oven. **Brandy-**

snaps.—7ozs. each flour and butter, 10ozs. sugar, 12ozs. golden syrup, 1oz. ground ginger. Mix well sugar, flour, and ginger. Melt butter and syrup, and pour on to the dry ingredients. Stir well until smooth. Bake in small pieces, about $\frac{1}{2}$ a teaspoon, in a moderate oven. Curl when nearly cool. *Cream Biscuits*.—7ozs. flour, 4ozs. each pounded sugar and butter, 1 tablespoon cream, 1 egg. Mix well. Roll out thinly. When cooked join together with any desired filling. *Crisp Nutties*.—1 cup each plain flour, flaked oats, dessicated cocoanut, 1 tablespoon golden syrup, 2 tablespoons boiling water, 1 teaspoon C. soda, $\frac{1}{2}$ lb. butter, 1 cup chopped nuts. Mix dry ingredients together. Dissolve syrup, butter, and c. soda in boiling water, and mix all together. Drop teaspoonful on slide and bake. *Cocoanut Biscuit*.—1 cup S.R. flour, $\frac{1}{2}$ cup sugar, 1 tablespoon butter, 1 egg. Roll out, spread with jam, and then spread mixture of $\frac{1}{2}$ cup sugar, $\frac{1}{2}$ cup cocoanut, and 1 egg on top. (Secretary, Miss G. Frost.)

WARRAMBOO.

June 23rd.—Attendance, 10.

THE KITCHEN GARDEN.—Miss E. Steer read the following paper:—"Every home should have a small garden growing vegetables for kitchen use and a few flowers to make the home bright. Not every district has water to use on a garden, but during winter such vegetables as turnips, carrots, cabbages, cauliflowers, onions, lettuces, silver beet, red beet, herbs, a small bed of shallots, thyme, mint, and parsley are a great asset to the kitchen. These can be grown around the tank or in tins where the waste water from the tap can run on them, and there will be plenty all the year round for flavoring soups, sauces, &c. In summer a few tomatoes, cucumbers, melons, and different kinds of marrows in well-worked beds can be grown; these do not need an abundance of water. Of the flowers, geraniums, daisy bushes, and carnations take very little water and always provide a few flowers for the table. The sandy soil will grow almost any kind of vegetables and flowers with care and a little work. Do not forget to have a strawberry and tomato patch for the hot days; they are the daintiest of dishes and very easy fruits to grow." (Secretary, Mrs. M. Steer.)

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences.

Branches of the Agricultural Bureau have been advised that a District Conference will be held as follows:—

Non-Irrigated Fruit Areas, at Nuriootpa, Tuesday, November 7th (Secretary, Mr. C. A. Verrall, Light's Pass).

The Conference will commence at 10.30 a.m.

Kybybolite Field Day, November 10th.

Grafting Affinity of Tokay on Shiraz.

The Viticultural Instructor at Roseworthy Agricultural College (Mr. J. L. Williams), in replying to a query from the Koonunga Branch of the Agricultural Bureau as to the advisability of grafting Tokay on Shiraz, says:—"There is no definite information regarding the grafting affinity between the two varieties mentioned, but so far as my personal observations are concerned, the Shiraz as a stock for grafting purposes is nearly always successful, and the union should prove quite satisfactory. It is advised that the grafting be done some 4-6 inches below the surface soil, providing the stems of the vines will permit the grafting to be carried out at this depth, and also that the soil is comparatively light in texture. It is essential, however, to graft on a portion of the stem which permits a clean placement of the scion variety (Tokay). For very heavy soil it would be best to do the grafting 3-4 inches below the surface soil and to fill in the hollow with a lighter textured soil, forming a complete mound over the graft to a height of 4 ins. above the surrounding soil.

Method.—Tokay cuttings are best buried in a sandy soil for at least a week before use for best results. Grafting is a long and tedious job and demands fairly careful work, so that I should advise not to attempt too much in one season—say 1-2 acres at the outside. This would depend, of course, upon the time and labor one is prepared to give the job. The best time for performing the operation would be about the middle of September or just about the period of bud burst. Saw the stocks off at a spot on the stems where clean unions can be made. Split the stocks down the centre with a grafting chisel provided with a fairly thin blade (can be conveniently made out of an old chaffcutter blade) and hold the cleft open far enough with a narrow wooden hard wedge, to allow two scions to be inserted, one on either side of the stem and flush with the smooth inner bark. Scions should be prepared as follows:—Use average-sized Tokay cuttings and prepare scions, carrying two buds in the form of a double wedge, and commencing the sloping section close to the lower bud and make same about 1½ ins. long. Push two scions in each cleft, one on either side of the stem and flush with the inner bark, and remove the wedge to hold scions firmly in place. Cover the cut surface with a piece of waxed paper to exclude moisture and cover the whole with a mound of earth 3-4 ins. above the normal soil level. Waxed paper can be made by dipping sheets of newspaper in molten grafting wax, made up as follows:—Beeswax 2 lbs., resin 4 lbs., fat 1 lb., linseed oil 1 pint. Melt all together in a suitable container.

Stock shoots or suckers must be periodically removed during the growing season, replacing the mound each time. The mound can be removed at the end of the season or as soon as the scion growth is satisfactory.

Cherry Tree Fungus.

A fruit tree fungus submitted by the Ramco Branch of the Agricultural Bureau to the Chief Horticultural Instructor (Mr. G. Quinn) has been identified as the fructifying stage of the common wood destroying fungus (*Polystictus cinnabarinus*, Fr.), which is

so destructive on stone fruit trees, particularly the cherry and apricot. Mr. Quinn says this fungus almost invariably finds an entrance into the trunk of limbs through unhealed wounds, made by pruning off branches or bruising the bark. In wet districts it frequently enters by reason of bruising made by fruit pickers or pruners standing on the top surfaces of horizontal limbs. In hot districts where bark is killed by sunscald on the top side of a limb, the spores find an entry. When the vermilion-colored bracket is seen protruding through a crack in the bark considerable damage has already taken place. If the dead surface bark be removed, it will be found that the wood beneath has been killed and decomposed into a soft puffy mass.

If seen soon enough, a valuable limb may be saved by excavating out all of the dead decomposed tissue right into the healthy wood, painting the wound with Bordeaux paste, and filling the cavity with cement smoothed to shed water when rain falls.

This is a fungus which may largely be prevented from gaining an entrance to the trees, if bruising be avoided, all pruning wounds be smoothed well, and thickly coated with white lead paint soon after they are made so as to stave off moisture and infection. Where these precautions are observed, and the trunks and limbs of trees are sprayed very thoroughly with Bordeaux mixture or some copper spray each autumn or spring, this fungus seldom obtains a serious foothold.

Algerian versus Early Burt Oats.

Replying to the Secretary of the Butler Branch of the Agricultural Bureau, who asked which oat has the better feeding value for horses, Algerian or Early Burt, the Deputy Director of Agriculture (Mr. W. J. Spafford) says the analyses of hays made of Algerian and Early Burt Oats give the following results:—

	Algerian Oats. Per cent.	Early Burt Oats. Per cent.
Moisture	6.25	6.20
Ash	6.04	5.89
Protein	6.74	5.10
Fat	2.90	2.99
Nitrogen-free extracts	49.27	48.97
Fibre	28.80	30.85
Digestible protein	5.06	3.83
Digestible fat	2.06	2.12
Digestible carbohydrates	31.04	30.85
Digestible fibre	17.28	18.51
Starch equivalent	40.3	39.1
Nutrient ratio	1 to 10.4	1 to 14.1

The figures show that these two hays are very similar in nature. As fattening food-stuffs they are almost identical, the starch equivalent figures being 40.3 for Algerian and 39.1 for Early Burt; but for the production of work, as is required from horses, the Algerian oat hay should be the better of the two because its nutrient ratio is only 1 to 10.4 against a ratio of 1 to 14.1 for Early Burt hay.

Lice in Horses.

Replying to a member of the Geranium Branch of the Agricultural Bureau who reports trouble with lice in horses, Mr. A. H. Robin, B.V.Sc., of the Stock and Brands Department, suggests the following treatment:—“Choose a warm, sunny day (which will bring the lice out more on to the surface of the coat) and wash the affected animal all over thoroughly with warm water to which has been added 2 per cent. lysol or 2 per cent. Cooper's milk oil fluid. Apply the wash with an old scrubbing or body brush so that it can be worked well in through the coat to the roots of the hairs. Then dry out as thoroughly as possible with an old towel or rag. Repeat the washing two or three times at intervals of 9-10 days. If the animals are stabled, so that these premises are liable to be also infested, they should be thoroughly cleaned of all manure

and litter, and then the floor, walls, and fittings well sprayed with kerosene solution. To make this take:—Hard soap, 1lb.; kerosene, 2galls.; water, 4galls. Dissolve the soap in the water, and then add the kerosene, shaking thoroughly till the whole is emulsified. Use 1 part of this emulsion to 8 parts of water. The lysol or milk oil fluid wash will kill off the free lice when brought into contact with them by its application to the animal's coat and skin, but it will not destroy the 'nits' or eggs—no dressing will. It is necessary, therefore, to re-apply the dressing at intervals as above stated in order to kill off each brood of young lice as they hatch out of the 'nits' before they mature and start laying further lots of 'nits'."

VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers, Stock and Brands Department.]

Clarendon reports cow third calf continually belching whilst being milked.

Reply—The eructation of gas is a frequent occurrence in cattle, and is normal. The frequency and amount depends on the feed. It is more frequent of greenfeed, especially clovers and lucerne. Unless the eructation is accompanied by "bloating" there is no necessity for medicinal treatment. If bloating is present, give 6ozs. of oil of turpentine well shaken up in 2 pints of fresh milk. Give this cow a ration of long hay daily, and a little chaff and bran at milking time.

Secretary, Springton Bureau, reports young sow with scales all over the body.

Reply—Choose a bright sunny day, and give the sow a thorough washing all over with soap and warm water in which has been dissolved 1 dessertspoonful of washing soda to 1 quart of water. Apply with an old scrubbing brush. When all scales, etc., have been removed by this washing, dry thoroughly. Remove pig to fresh, clean quarters, and subsequently twice weekly apply a light dressing to the skin of flowers of sulphur 1 part, lard 4 parts. Dress only about one-third to one-half the body at any one application. Give pig once a week 2ozs. of Epsom salts dissolved in warm milk or swill feed.

Hon. Secretary, Saddleworth, asks why do cows eat bark off trees when they receive an abundance of licks?

Reply—The condition of "pica" or depraved appetite is probably due to a chronic indigestion. It is suggested that if possible a change of pasture be given. A purgative drench should be administered, followed by a course of the following mixture:—Carbonate of iron, 4ozs.; sweet ground bonemeal, 1lb.; powdered gentian, 4ozs.; salt, 8ozs.; powdered fenugreek, 4ozs. One heaped tablespoonful of this mixture should be given three times daily. It should be noted that this mixture contains bonemeal and salt, therefore the administration of these medicaments by other forms (such as licks, &c.) should for the time being be discontinued. In addition to the above mixture give 2 tablespoons of powdered charcoal mixed in with damped feed 3 times daily.

Weavers Agricultural Bureau asks if a calf running with a cow that has mammitis would be affected.

Reply—The calf would not be upset unless the milk from the affected quarters was very bad. Allowing the calf to suckle the cow would, however, very likely serve to spread the trouble to the other quarters of the cow's udder.

Brentwood Agricultural Bureau reports mare 12 years old, paws ground with front legs, and is alternately scoured and constipated.

Reply—The symptoms are those of an indigestion. Give the following drench:—Raw linseed oil, 1½ pints; turpentine, 4 tablespoons; lysol, 1 teaspoon. Failing this give 1lb. honey or 1 pint of new milk. Subsequently give 1 level teaspoon of powdered

the one oil that always
stands up

nux vomica on back of tongue three times a day for a few days. Feed lightly on easily digested feed, and give 1 tablespoon of Fowler's solution of arsenic in damped feed night and morning for a fortnight. If possible, also have animal's teeth examined and attended to if necessary.

Palabie Agricultural Bureau has horses with cough, slight discharge from nose, and offensive breath.

Reply—The trouble may be due to an infection of the sinuses of the head, to a diseased tooth, or to a piece of diseased bone at the back of the nose. There is little that can be done in the way of treatment except to control the offensive smell to some extent by steaming the nostrils with steam medicated with eucalyptus or turpentine.

Gawler asks treatment for mares which have not been bred from for some time and are difficult to get in foal.

Reply—The following procedure should be tried:—(1) "Flushing" of the mare by giving better (more nourishing) food. (2) Putting the mare to the stallion towards the end of the heat. (3) One hour prior to service the outer passage should be douched out with a solution of bicarbonate of soda (1 dessertspoonful to each pint). Use solution at blood heat. At the same time rake out any mucus present in the passage. (4) Keep mare quiet (no work) both before and after service. If standing after service, throw cold water over loins and hindquarters. (5) If it is possible to let the mare run in the paddock with a young stallion, there is a much better chance of getting her in foal.

Nunkeri reports:—(1) Horse with persistent cough and discharge from nose and mouth, rough coat, and sluggish at work. (2) Pigs 7 months old making no headway.

Reply—(1) The persistent coughing is probably due to a chronic indigestion. Throw the animal out of work for a few days. Starve for 24 hours, and then place on back of tongue 1 dram calomel and $\frac{1}{2}$ dram aloin. If these drugs are not obtainable, as an alternative give a drench of raw linseed oil, 1 $\frac{1}{2}$ pints; turpentine, 4 tablespoons. Subsequently feed on well damped bran and chaff with a daily allowance of greenfeed. Get a 1lb. bottle of Fowler's solution of arsenic, and give 1 tablespoon in damped feed night and morning until it is all used. See that rock salt is constantly supplied in the feed manger. (2) Wheat, chaff, and water is not an adequate diet for young growing pigs. Cut out the chaff ration and substitute grazing on greenfeed in lieu of it. If skim milk is available feed it liberally, but if not add 5 per cent. linseed meal or meat meal to the diet. One teaspoon of sweet ground bonemeal should be also fed per pig daily mixed in with the trough feed.

Weavers Agricultural Bureau reports 3-year-old gelding lame in hind leg, fetlock swollen.

Reply—Try the following treatment:—Obtain the following lotion from a chemist:—Take lead acetate, 1oz.; zinc sulphate, $\frac{1}{2}$ oz.; water, 2 pints. Dissolve the lead salt in 1 pint of water, the zinc salt in the other pint, mix together, place in a bottle, and shake before use. *To use.*—Have a pad of wool sufficient to go round the fetlock joint and swelling; pour a little of the solution on it; apply to the joint, and bandage fairly tightly, removing once daily and replacing. For a week keep the animal at rest in a stall.

Narridy reports difficulty in getting cows in calf.

Reply—The failure to breed on part of the cows may be due to vaginitis, which disease is very contagious, and readily spread from one cow to another through service by the bull. Try the following treatment:—Douche breeding passage of cows every third day with 1gall. of warm Condry's solution (strength, $\frac{1}{2}$ level teaspoon of crystals to 1gall. water). Continue this treatment until the animals come "in season" again. Then douche with 1gall. of warm baking soda solution $\frac{1}{2}$ hour before service. (Strength of solution, 2 heaped teaspoons of baking soda to 1gall. water.)

RESUME OF 12 YEARS PASTURE EXPERIMENTAL WORK AT KYBYBOLITE.

(Paper read by Mr. L. J. Cook, R.D.A., Manager Government Experimental Farm, Kybybolite, at the 44th Congress of the Agricultural Bureau, September, 1933.)

The situation of the work is in our mid South-East, within the 20in. rainfall zone (average falls have been 20½in. per annum for the 12 seasons, 1921-32, inclusive) on soils typical of large areas, rather poor in natural fertility, particularly in regard to the minerals—lime and phosphorus.

Poor physical conditions of soil cause difficulty in growing cultivated crops. Uncertain maturation of cereals, combined with the necessity to build up the organic content of the soils, led to the adoption of livestock as the main farm project.

Pasture being the most important and economical food for livestock, primary attention has been given to pasture development, and our principal experiments have dealt with fertilising of grasses and clovers.

In 1919 our first work of this nature was commenced by top dressing six plots of natural pasture, and to these, 11 plots have been added at various times, and we have complete grazing results from all of these plots during the past 12 seasons, and for the immediate past four years we have studied the development of Comeback ewes, the breeding of lambs, and the production of wool from these variously fertilised natural pasture plots.

Early in this decade we realised the importance of Subterranean Clover, demonstrated by our neighbor, Mr. S. Shepherd, and in 1924 a manurial test was set out on 15 plots of this clover. Recognition of the fact of balancing the pasture ration was observed and Wimmera Rye Grass was sown with all plots of Subterranean Clover in 1924 and in most fields since.

Small trials of all known introduced species of grass, deemed possibly suitable, have been made at different times. *Phalaris tuberosa* has persisted and thrived against all weed competition and grazing conditions for eight seasons. The only other introduced perennial grasses to persist for six or more seasons have been Kikuyu and *Paspalum* grasses, but these only make growth in the warm months of the year; the former quite an appreciable amount, which may lead to its future use on small areas, but the latter makes insufficient growth to warrant consideration.

In carrying out our pasture experiments, reasonable size of plots was adopted, areas from 3½ to 5 acres each, so that each could be treated more or less as a practical field of the farm. Therefore, over a course of years, a true stock carrying capacity can, and has, been obtained, and moreover, we have been able to run sufficiently large flocks to study the development and production of livestock. Also plenty of scope is available for obtaining analytical samples of both soil and plants.

RESULTS OF PASTURE WORK.

THE VARIATION OF PLANT SPECIES AND PERIOD OF GROWTH.

Our virgin soils carry a sward of principally isolated plants of Wallaby (*Danthornia* species), interspersed with a few plants of Spear Grass and tiny plants of naturalised clover. A fair quantity of *Juncus*, moss, and other useless plants are also present. During wet and cold conditions of winter this pasture becomes very dejected; the grass browns off, and is very sickly. Whilst the grass is growing and green sheep gain weight, and produce a fine quality wool, but the dry stalks of summer period are not relished by stock.

When such pasture is improved by top-dressing with phosphates, or with phosphates and lime, there is a gradual alteration on the pasture growths. There is an immediate brightening in appearance, and a fairly quick development of annual naturalised clovers. By the third or fourth season of applications annual clovers will be dominant, and the field covered by a complete sward, consisting of annual clovers and grasses with the rooted Wallaby Grass. The *Juncus*, moss, and other useless plants become subjected, and gradually disappear. In later seasons the annual grasses become more dominant, and the percentage of clovers recedes back to approximately 20 per cent. to 30 per cent. The *Danthonia* plants persist, and increase in health and vigor. The period of growth is earlier, a very quick response being gained from autumn and early winter rains. Although growth is checked in mid-winter, on well-fertilised pasture this check is of much shorter duration, and plants quickly recover and maintain better health. The annual grasses tend to earlier maturity in the spring, and the type of dry feed available in the late summer is not good for maintaining stock in condition. Of later years geranium has appeared in fair quantity on some of the heavier fertilised plots.

These soils when ploughed, cultivated, and sown to Subterranean Clover with sufficient phosphatic fertiliser will quickly establish a sward of dominant clover in two seasons. Practically all natural plants are destroyed. The dominance of clover will disappear after a few seasons, and grasses, such as Sterile and Soft Brome, Barley, and Silver Grass become plentiful. These annual grasses are restricted where Rye grasses or *Phalaris tuberosa* are grown with the Subterranean Clover.

INCREASE IN QUANTITY OF FEED.

This is instanced by the complete thickening of the sward, the greater growth, and subsequent greater carrying capacity. On all top-dressed natural pasture for 12 years there has been an increase of 1.36 sheep per acre per annum over virgin land, and for the immediate seven seasons there has been an increase of 1.58 sheep per acre. On all sown Subterranean Clover and Wimmera Rye Grass pasture plots for the immediate eight seasons there has been an increase of 2.37 sheep per acre per annum over virgin land. The above are the averages of all fertilisations. The best plots have shown increases of 2.33, 2.57, and 3.44 sheep per acre respectively.

IMPROVEMENT IN QUALITY OF FEED.

This is shown by the earlier maturity and greater development of livestock grazing on the improved pastures, the higher lambing percentages, greater wool production of sheep, and the greater milk production of cows. As regards maturity Comeback ewes grazed on virgin land were three years of age before they reached an average live weight of 100lbs. each. Similar type ewes grazed on top-dressed virgin land reached 100lbs. live weight at 27 months of age, whilst others grazed on well-fertilised Subterranean Clover and Wimmera Rye Grass pasture were 100lbs. live weight at 14 to 15 months of age.

With reference to greater development, ewes grazing on sown pasture for three seasons (two-tooths) have shown 16 per cent. greater average live weight than similar ewes grazing improved natural pasture; for two seasons four-tooth ewes have shown 23 per cent., and for one season six-tooth ewes have shown 21 per cent. greater average live weight. Hence it is definite that on sown pasture ewes show 20 per cent. better development than on top-dressed natural pasture. Comparing similar type ewes for two seasons on virgin land and improved top-dressed virgin land, we find that six and eight tooth breeding ewes have maintained 10 per cent. better average live weight (106.22lbs.) on the latter, against 96.88lbs. on unimproved pasture.

As regards lambing, for two seasons the percentage of marked lambs has been 19½ per cent. better from sown pasture than top-dressed natural pasture, and for three seasons the percentages from top-dressed natural pasture have averaged 40 per cent. greater than from virgin land. The weights of lambs at weaning from sown pasture have been 24 per cent. greater than from improved natural pasture. Those from improved natural pasture, however, were 7 per cent. lighter than those grazed on unimproved land. This is undoubtedly due to the rapid ripening of annual naturalised grasses and clovers, and their poor nutritional qualities when dry. The lambs were all dropped in the spring.

The wool production from sown pasture has been 21 per cent. greater per head from two-tooth ewes (three years average), 14 per cent. greater from four-tooth ewes (two years average), and 3 per cent. greater from six-tooth ewes (one year only) than from ewes on improved natural pasture. This is an all round average increase of 12½ per cent. per head in weight of wool. The production per head from top-dressed natural pasture compared with unimproved pasture has not been great. During a three-year period the difference has been only 4 per cent. in favor of top-dressed land.

Comparative figures are not available for milk production, as virgin land is not at all suitable for cattle, and top-dressed natural pasture would be suitable only for a short period of the year. Sown pastures of Subterranean Clover, Rye Grass, and *Phalaris*, however, are proving very good for the carrying of milking cows, and some high production figures are being produced from these pastures.

IMPROVEMENT IN SOIL TEXTURE AND PHYSICAL CONDITION.

This is obvious, as the vast extra amount of root growth produced in the soil from the complete swards of pastures is gradually binding the soil and increasing the organic content so that stock can graze over the land at practically any period of the year, irrespective of the amount of rainfall. The soil becomes a better medium for life, consequently bacteria and living organisms are vastly increased in the improved soils. Further, the improvement enables cultivation of the soil to be done earlier in the spring and later in the autumn without risk of breaking down the soil texture.

RESULTS OF VARIOUS FERTILISERS ON THESE PASTURES.

SUPERPHOSPHATE.

Superphosphate is undoubtedly the most important fertiliser. Improvements can be obtained with various clovers and grasses, but without liberal dressings of phosphatic fertilisers results will be small, and water soluble phosphate is the best as it is most economical for quick returns. Quantitative test on both natural and sown pasture are being carried out with the following results up to date:—

Fertiliser per Acre.	Natural Pasture. (4yrs. average.) Sheep per Acre.	Fertiliser per Acre.	Sown Pasture. (5yrs. average.) Sheep per Acre.
51lbs. super. (10½lbs. phos. acid)	2.88	45lbs. super. (9½lbs. phos.)	2.91
90lbs. super. (18½lbs. phos. acid)	3.25	90lbs. super.	4.42
180lbs. super. (37lbs. phos. acid)	3.45	180lbs. super.	4.98
No manure	0.92	No manure	1.15

These results have been compiled from figures obtained during the immediate past four and five years, that is, the first few years of development have not been considered, so that the figures show the results obtained when various quantities of 45 per cent. superphosphate have been applied to established pastures. The figures decisively show that the more water soluble phosphate applied the

greater has been the return in feed. The most economic amount to apply at present prices would appear to be 90lbs. 45 per cent. superphosphate per acre annually. They also show that much greater return is secured from this superphosphate when used on Subterranean Clover sown pasture.

The next table shows the increase in sheep carried and money value when 90lbs. 45 per cent. superphosphate has been applied to both pastures for nine seasons in succession. Figures have been taken from the year of commencing. The annual cost of superphosphate has been averaged at 5s. 6d. per acre to cover cost of freight and application to the land, and sheep have been valued at the low average price of 10s. each per annum.

	Natural Pasture.				Sown Pasture.			
	Increase above No Manure. Sheep per Acre.	Value.			Increase over No Manure. Sheep per Acre.	Value.

8th year ...	2.76	27/7	"	22/1	3.98	39/9	"	34/3
9th year ...	2.85	28/6	"	23/-	3.30	33/-	"	27/6
%increase ..	207%				172%			
Total profit				83/2				152/8
Profit per year per acre				9/3				16/11

If an allowance of 25 per cent. is made for the size of fields the profits would still show at approximately 7s. and 12s. 8d. per acre per year. Further, the above does not take into account the increased individual value of sheep and wool produced, so that actually the profit would be greater. With sheep on virgin land valued at 10s. each those on sown pasture would be easily worth 12s. each. The next table shows the production of Comeback ewes for the first three years of life, comparing Flock A (nine ewes) reared on unfertilised clover and natural pasture, with Flock B (26 ewes) reared on natural pasture fertilised with superphosphate, and with Flock E (20 ewes) reared on clover pasture fertilised with superphosphate:—

	Flock A on Unmanured Pastures.	Flock B on Natural Pastures Fert. with Super.	Flock E on Clover Pastures Fert. with Super.
Average monthly live weight of ewes from 8 months to 3 years old	87.80lbs.	90.91lbs.	106.88lbs.
Average yearly wool production per head	8lbs. 2ozs.	8lbs. 4ozs.	9lbs. 5ozs.
Average lambing percentage (2 years)	55%	74%	83%
Sheep carried per acre annually.....	1.09	3.19	4.20

The sheep in the above flocks have been wholly grazed on their respective types of pasture, and have received no other feed or licks. They have been grazed under a rotational system, and only for short periods during the mating seasons have they grazed elsewhere than on the plots assigned to them.

The wool production per acre per annum of the three flocks has been as follows:—

	8lbs. 14ozs. from unmanured pasture.
	26lbs. 5ozs. from natural pasture plus superphosphate.
	39lbs. 2ozs. from Clover and Rye pasture plus superphosphate.

LIME AND SUPERPHOSPHATE.

Lime has been used at the rate of 1 ton per acre on pastures every 10 years and combined with usual applications of superphosphate. One plot (P3) of natural pasture was dressed with lime in 1919 and 1929, and has received 1cwt. 36 per cent. superphosphate annually. Another plot (P10) of natural pasture was dressed with lime in 1924, and has received 1cwt. 45 per cent. superphosphate annually. One plot (C7) of Subterranean Clover and Wimmera Rye Grass was dressed with lime in 1924, and has also received 1cwt. 45 per cent. superphosphate annually. The grazing results from these are summarised as follows:—

	Sheep Carried per Acre per Annum.	Increase Over No Manure.	Increase Over Super. only.
Plot P3, 12-year mean.....	3.15	2.33	0.82
Plot P10, 7-year mean.....	2.81	1.92	0.17
Plot C7, 8-year mean	4.36	3.47	0.36

Results show a large improvement over no manure, but only a comparative slight increase over superphosphate dressed plots. The feed, however, on these limed plots has been earlier, and has contained a higher percentage of grass to clover than phosphate only dressed plots. More feed has been provided during the winter months where lime has been applied. Particularly has this fact been evidenced on the sown pasture, where annual grasses have grown more strongly and in greater dominance. The following two graphs show an interesting comparison of the effect of lime and superphosphate with superphosphate only on Subterranean Clover pasture.

Graph 1 shows a greater production of feed from superphosphate only during the early years of application, but the steady and continued increase of feed from lime and superphosphate shows a greater production during the last four seasons.

Graph 2 shows the average monthly grazings received for eight seasons from the two fertilisings, illustrating the better carrying capacity of the lime and superphosphate dressings during the months of June, July, and August.

The next table shows the production of Comeback ewes for the first three years of life, comparing Flock A on unmanured pasture with Flocks C and I reared on natural and clover pasture respectively, both fertilised with lime or gypsum and superphosphate.

	Flock A on Unmanured Pastures.	Flock C on Natural Pastures Fert. with Lime and Super.	Flock I on Clover Pastures Fert. with Lime and Super.
Average monthly live weight of ewes from 8 months to 3 years old	87-80lbs.	93-18lbs.	107-84lbs.
Average yearly wool production per head	8lbs. 2ozs.	8lbs. 7ozs.	9lbs. 3ozs.
Average lambing percentage (2 years)	55%	80%	76%
Sheep carried per acre annually.....	1.09	3.45	4.92

When these figures are compared with the similar table given under heading of superphosphate, it will be noticed that there is not much variation individually between ewes reared on lime and superphosphate fertilised land with those reared on land fertilised with superphosphate only. On account of the extra sheep carried per acre, however, the yield of wool per acre is greater from lime and superphosphate dressed pasture as shown by following figures:—

26lbs. 5ozs. super only.	29lbs. 1oz. natural pasture plus lime and super.
39lbs. 2ozs. super only.	45lbs. 3ozs. from clover pasture plus lime and super.

These small increases of 2½lbs. and 6lbs. respectively show that unless a cheap source of agricultural lime is available the expense of its use is not at present warranted on these sheep pastures.

Graph 1.—Showing Comparison of Sheep Carrying Capacity on Subterranean Clover and Wimmera Rye Grass Pasture Fertilised with Lime and Super and Super only, 1925-32.

Graph 2.—Showing Sheep per Acre Carried Monthly for 8 Years, 1925-1933 on Subterranean Clover and Wimmera Rye Grass Plots, Nos. 7 and 15.

CRUSHED ROCK PHOSPHATE.

Local low-grade rock phosphates of both aluminium and calcium phosphates have been tested from six to 10 years on natural pasture, and the 82 per cent island phosphate has been tested on both natural and sown clover pastures.

Comparing the results of the two low-grade rocks over a 10-year period aluminium phosphate carried 1.83 sheep per acre, and over the same period a similar dressing of calcium phosphate carried 1.87 sheep per acre. A small difference from which it is apparent that phosphorus is the all-important substance, and that the base with which it is combined has only a small if any effect.

In using this acid soluble form of phosphate as it occurs in rock phosphates it is necessary to apply fairly large quantities initially, and either follow with large quantities at comparatively long intervals or follow with small applications annually. The effect of these dressings on natural pasture so far favors the former, as the greatest return has been received from large applications applied every 10 years, as the following figures show:—

	Sheep Carried per Acre. (12yrs. average.)	Increase over No Manure.	Per Cent. Increase.
Calcium phosphate rock—			
Two applications, 10 years apart—420lbs. phos. acid per acre each application	1.98	1.16	141
The same fertiliser—232lbs. phos. acid applied initially and 21lbs. applied annually since	1.85	1.03	125
Check plot—No manure	0.82	—	—

These results show good improvement but not nearly as much as given by water soluble phosphate. As a definite comparison of water and acid soluble phosphates consider Plots Nos. P2 and P4. From 1919-25 these had received approximately the same amount of phosphoric acid in the acid soluble form, namely, 351lbs. to P2 and 359lbs. to P4, and both had carried approximately the same stock, 1.73 and 1.76 sheep per acre per annum. Commencing in 1926 an application of 51lbs. water soluble, that is 10½lbs. phosphoric anhydride, has been given annually to Plot P2 whilst P4 has continued to receive 56lbs. island phosphate, that is 21lbs. acid soluble phosphoric anhydride annually, just twice the quantity of phosphorus. The grazing for the subsequent seven seasons shows P2 1.65 sheep per acre better than the check plot, and P4 1.03 sheep per acre better, which is a 60 per cent. increase in favor of water soluble phosphate even when applied in half the quantity.

The results of applying island rock phosphate to Subterranean Clover and Wimmera Rye Grass pasture are as follows:—

	Sheep per Acre. (8yrs. average.)	Increase over No Manure.	Per Cent. Increase.
Rock phosphate (two plots) equal 28.7lbs. phos. anhydride annually	3.28	1.81	123
Superphosphate (three plots), 26lbs. phos. anhy- dride annually	4.05	2.58	175

These results show that the sown pasture responds better to phosphatic fertiliser in the water soluble form.

EPHOS PHOSPHATE (61 PER CENT. PHOSPHATE).

In 1924 two five-acre plots were dressed with this fertiliser, one of natural grass, and one of sown clover and rye grass. Each plot received a 6cwts. per acre dressing, approximately 188lbs. phosphoric anhydride, 82 per cent. of which would be in the acid soluble form, about 16 per cent. citrate soluble, and 1½ per cent. to 2 per cent. water soluble.

Grazing figures are available from 1925, and are as follows:—

	Sheep per Acre, 8 Years Average.	Increase Over No Manure.
Natural Pasture	2.02	1.14 (130%)
Sown Pasture Subt. Clover and Rye Grass	4.00	2.53 (172%)

These returns show this fertiliser to have yielded almost equal to superphosphate on sown pasture, but only slightly better than rock phosphate on natural pasture. The average of the two, therefore, shows that the yield from the fertiliser is somewhat commensurate with the availability of its phosphate content.

CRUSHED LIMESTONE AND SUPERPHOSPHATE.

In 1926 one five-acre plot of natural pasture was dressed with 1 ton crushed Mount Gambier limestone per acre, and has received 1cwt. superphosphate annually since. The mean sheep carried per acre for seven seasons has been 2.78, which is 1.89 more than check plots over the same seasons, and only 0.14 more than superphosphate dressed plot. The yield is slightly less than that from lime and superphosphate, and future yields will be noted to see whether the limestone will have the same lasting and increasing benefit secured from lime.

GYPSUM AND SUPERPHOSPHATE.

Also in 1926 a dressing of 1 ton gypsum per acre was applied to a plot of natural grass, which has also received 1cwt. 45 per cent. superphosphate per annum. The mean sheep carried for seven seasons has been 2.42 per acre or 1.53 more than check plot of no manure but less than superphosphate only plot.

In 1928 a plot of sown clover and rye was dressed with gypsum and super, resulting in a mean yield over five seasons of 4.65 sheep per acre, compared with 4.97 for lime and superphosphate, and 4.42 for superphosphate only. So far as results show at present gypsum is not as productive as agricultural lime.

POTASH.

Potash has been tested on sown pasture for eight seasons, applying 37lbs. 90 per cent. sulphate of potash per acre per annum to two five-acre plots, one solely dressed with potash, and the other dressed with rock phosphate as well. The grazing results from these have been:—

	Sheep per Acre per Annum.	Increase Over No Manure.	Increase Over Rock Phosphate Only.
Potash-dressed plot	2.32	0.85 (58%)	—
Potash and Phosphate dressed plot	3.54	2.07	0.48 (16%)

These results show increases of $\frac{1}{4}$ to $\frac{3}{4}$ sheep due to potash, which would cover cost of fertiliser, but nevertheless the same money spent on superphosphate would bring in much greater return.

NITROGEN.

Of recent years work has been commenced with artificial nitrogen fertilisers in conjunction with the Nitrogen Fertilisers Pty., Ltd. For two seasons on Subterranean Clover and Wimmera Rye Grass pasture on a series of eight four-acre plots, nitrogen and superphosphate have been tested against superphosphate only. Both sulphate of ammonia and calcium nitrate fertilisers were used, and a noticeable difference in quickness of growth was caused by the nitrogen, although no variation could be detected between the effects of the ammonia and the calcium nitrate. The pastures on all eight plots were good, well established some five seasons earlier, and cattle were used to graze them. For the two seasons the nitrogen and phosphate dressed plots average nearly $\frac{1}{2}$ cow per acre (0.48), and the four phosphate only plots carried 0.41 cows. This gain of 0.07 cow per

acre per year (17 per cent. increase) scarcely covered cost of fertiliser even when allowance was made for the slightly better feed available in the winter months. Further work with these fertilisers is being carried out on sown pastures of certified Perennial Rye Grass, *Phalaris tuberosa*, and Clover.

PERENNIAL GRASSES.

The foregoing shows that fertiliser and Subterranean Clover have greatly improved the growth of grass and livestock. The naturalised grasses that have benefited are principally Sterile Brome, Barley, and Silver grasses. These provide useful winter and early spring feed, but mature early, providing dry feed in the summer, which is not of best quality, and has objectionable seeds that trouble livestock. By judicious use of the mower a lot of this growth can be conserved in a nutritional and palatable state, as ensilage or hay. By sowing Wimmera Rye Grass in the fields, a strong competitor against the naturalised grasses is available, and the objectionable seed trouble can be reduced.

Perennial grasses have a better ability to compete and subject annual plants, and some work has been done to find types or strains of perennial grasses able to produce the quantity of food, and persist under present fertility and climatic conditions. They respond quicker to summer and autumn rains, and provide a useful bite of green when much needed; but it is important that this be not provided at the expense of subsequent winter feed. From trials so far, only two perennials appear to be suitable, namely, *Phalaris tuberosa* and Perennial Rye Grass.

PHALARIS TUBEROSA.

Phalaris tuberosa has proved exceptionally persistent in small trials, and in 1930 a five-acre plot was established to give it proper field trial, and indications show great promise of it providing, with Subterranean Clover, the good quantity of feed, persisting well, and keeping the annual grasses somewhat in subjection.

The grazing result for the three seasons has been:—

1930-31	1.64 sheep per acre
1931-32	3.52 sheep per acre
1932-33	3.82 sheep per acre

These results, obtained from bare fallowed virgin land, show as quick production of good class pasture as yet obtained. Plants were well established by using only 2lbs. seed per acre, and up to date there has been no noticeable death of plants. They have lived through three summers and four winters quite successfully. This winter there was only a slight browning of a small portion of leaves of the plants. Subterranean Clover is growing well amongst the plants of grass, and providing ample nitrogen for their use. The field has received 1cwt. 45 superphosphate annually. It is important to mention that thorough soil preparation is necessary to establish this grass, the soil needs to be clean and in good condition, and seed sown on a well-prepared bed.

Wimmera Rye Grass sown under similar conditions as above plot has not given greater quantity of feed.

In fact, the results compare equally favorable with the best returns secured from Wimmera Rye and Subterranean Clover established on old cultivated land.

PERENNIAL RYE GRASS.

Perennial Rye Grass has given some useful results. It makes quickest response from summer and autumn rains, but does not maintain the healthy winter growth of *Phalaris tuberosa*, or the annual grasses. Trials in the past with commercial seed have shown a lack of ability to persist after the third season. Of recent seasons certified New Zealand seed has been used, and it is hoped that by the aid of clover growths to keep sufficient nitrogen supply up to the Perennial Rye

plants, and enable them to make longer life. The browning off, and, in extreme cases, the death of Perennial Rye grass plants during the winter months, is a serious matter under our conditions, and emphasises the necessity for readily available organic nitrogen. Factors most apparent at the present stage of our work are:— Firstly, the strict importance of growing clover with Perennial Rye; and secondly, the obtaining of comparatively thin stands of plant, with seedings of 2lbs. to 4lbs. certified seed per acre.

Work is in hand in conjunction with the Australian Dairy Council, trying out many strains of Perennial Rye and *Phalaris*, and it is anticipated to make careful selection of strains that are highly productive and persistent.

TEMPORARY PASTURES.

Some work on temporary pastures of one, two, three and four years' duration is being carried out amongst our various rotational cropping tests, but little of a definite nature has yet been finalised.

Ploughing and cultivating soil has its sweetening action, that is, aerates the soil, and deepens the medium for growth of roots, and for the work of the bacterial life of the soil. Just how much, and how often cultivation is necessary for the best continuous production of our pastures is a matter needing a lot of further investigation, and will probably vary with the type of plants used in the pastures.

So far as our Kybybolite work has gone, we can definitely state that under our present state of fertility, at all events a one-year temporary pasture is not warranted. A number of types of plants have been tried as one year leas, such as Red Clover, Crimson Clover, and King Island Melilotus, and of these the latter where lime has been applied to the soil has given best results but not a substantial one.

Similarly a two-year pasture has not up to the present indicated satisfactory results. Plants tried under this system have been Subterranean, Alsike, Yellow Trefoil, and White Dutch Clovers, Sheep's Burnet, Italian and Perennial Rye Grasses, and of these Subterranean Clover and Perennial Rye have given greatest growth, but not nearly as much feed as when left for longer leas. Better initial soil preparation, with subsequent longer pasture duration, is warranted.

A three-year lea of Subterranean Clover has been tested for a number of seasons on 30-acre fields, with the following grazing results:—

	Sheep per Acre per Annum.
First year after crop (9 years mean)	2.53
Second year after crop (8 years mean)	2.59
Third year after crop (7 years mean)	2.76
Continuous grazing, Field 18 (8 years mean).....	2.70
Continuous grazing, Field 12 (7 years mean).....	2.78
Continuous grazing, Field 20 (5 years mean).....	2.55

The above results are approximate, as it has not been possible to maintain complete grazing of larger fields, similarly as we have done with experimental plots of five-acre areas. However, the figures indicate rather plainly that whilst Subterranean Clover fields have not been greatly reduced by breaking up the land for cropping after three seasons lea, the yields most certainly have not been increased. It is noticeable that the yield of pasture has been greatest during the third season after cropping in five seasons out of seven. Fields such as Nos. 12 and 18, which are of comparative size, and have received approximate equal fertiliser dressings and somewhat similar grazing conditions, have, under continuous grazing, maintained a greater annual carrying capacity.

We can conclude, therefore, that so far as Subterranean Clover pasture is concerned, provided it is top-dressed and handled well, there is no advantage to be gained in breaking up the soil at comparatively short intervals.

HEALTH OF STOCK.

Before concluding remarks on pastures, something relative to the health of livestock is perhaps appropriate. No definite work regarding the prevention or treatment of disease in stock has yet been undertaken on the farm, but of recent years a record of the losses of sheep on the pasture plots has been kept. Incidentally, the sheep grazing on these plots have been managed under the system of rotational grazing during the growing period of grass and clovers. This is essential both as an aid to the maintenance of health of both livestock and pastures.

Considering ewes that have been born and reared on the Subterranean Clover and Wimmera Rye Grass pasture plots and who have received no other feed than that obtained from these pastures, the losses for the past three seasons have been:—

		%
1930	2 deaths in flocks of 54 ewes	3.7
1931	7 deaths in flocks of 90 ewes	7.78
1932	4 deaths in flocks of 129 ewes	3.10
Average loss for 3 years		<u>4.86</u>

Of the above, the losses occurring amongst 1929 spring drop ewes have been 4.5 per cent., those amongst 1930 born ewes 7.7 per cent., and from the 1931 born ewes there has been no losses. All of these deaths occurred in the late winter and spring of the year, and the majority were apparently due to entero-toxaemia.

Considering ewes that have been reared on improved natural pasture, and who have received no other feed since eight months of age, the losses have been as follows:—

		%
1929	1 death out of 78 ewes	1.28
1930	0 deaths out of 89 ewes	0
1931	0 deaths out of 93 ewes	0
1932	2 deaths out of 101 ewes	1.98
Average loss for 4 years		<u>0.82</u>

Two of these deaths occurred in the spring and one in the summer, and were accounted to digestive disorder.

From the above results it appears that sheep grazed on natural pasture are the more healthy, but in general appearance of the sheep this is not so apparent. The loss of less than 5 per cent. on clover land is not great, and from an economic point does not much detract from the value of the pasture. When allowance is made for these losses, our results show increases of 28 per cent., 39 per cent., and 15 per cent. for 1929, 1930, and 1931 ewes respectively in wool production per acre for sown pasture over improved natural pasture.

MISCELLANEOUS PASTURE MATTERS.

PASTURE HARROWING.

Although some pasture harrowing, principally in cow paddocks, has been done, no definite experimental data has yet been collected.

ROTATIONAL GRAZING.

Some rotational grazing of plots by the milking herd, and a good deal by sheep, have been carried out during the past eight seasons on growing pastures, but no definite test has been set, or data collected.

MEADOW HAY AND ENSILAGE.

Ensilage and meadow hay have both been made from the pastures by modern methods, but, except for yield per acre over a few seasons, no data is available. In 1932 fields closed from livestock for three months of spring cut 9 tons 6½cwts. greenstuff per acre, which made a really first-class ensilage.

The average yield of meadow hay over the immediate past six seasons has been 1 ton 16cwts. 78lbs. per acre. In two seasons the yield has been over 2 tons per acre, and in only one season has the return been less than 32cwts.

DAIRYING.

One of the principal results of our pasture work has been the definite development of ¼ sheep per acre land into good dairying conditions. Good pasture makes first-class ensilage, and this enables succulent feed to be provided for milking cows during the whole of the year. Meadow hay, when properly made, is a very nutritious food, and provides necessary dry feed during the winter months. Oats and barley grains can readily be grown on the clover leas, and, with the possible exception of bran, all feeds necessary to produce a constant supply of milk all the year can be produced at comparatively cheap cost.

Under official test, our Ayrshire herd has produced the following figures during the past five seasons in connection with the State Gold Medal Competition:—

1928-29	24 cows	312-32lbs. butterfat per cow
1929-30	25 cows	308-68lbs. butterfat per cow
1930-31	28 cows	341-75lbs. butterfat per cow
1931-32	27 cows	327-92lbs. butterfat per cow
1932-33	29 cows	338-66lbs. butterfat per cow
Mean for 5 years		325-87lbs. butterfat per cow

These figures prove the suitability of present conditions for dairying, and as our herd of approximately 40 milkers only use 90 acres of sown pasture areas, it is significant that land which previously carried ¼ to ¾ sheep per acre is now producing from 100 to 150lbs. butter fat per annum.

FAT LAMB PRODUCTION.

A preliminary experiment has been commenced this season, testing the production of lambs from our Comeback ewes, mated with rams of the Suffolk, South-down, Dorset Horn, and English Leicester breeds.

BARLEY

We have large Overseas Representation, and are in constant touch with the World's Markets, and strongly advise Growers, before selling elsewhere, to submit samples to us for valuation.

Delivery taken at any Railway Station, Siding, or Shipping Port.

F. W. HANCOCK & CO.,

CRANBROOK CHAMBERS, BENTHAM STREET, ADELAIDE.

TELEPHONE: CENTRAL 4865 and 4866.

GRASS SEED PRODUCTION.

Trial of a comprehensive collection of strains, principally of Rye grasses and *Phalaris tuberosa*, was commenced in 1932. Details of their growths are being made, and subsequently selection and isolation of the best productive and persistent strains will be made. This work has been made possible through the grant made to us by the Australian Dairy Council.

The Waite Research Institute commenced work in conjunction with us in 1929, and various experiments dealing with pasture species and mixtures, manurial, sheep and wool production are in hand.

SUMMARY.

1. Top-dressing with phosphates causes a dominant growth of clover for a few seasons; subsequently grasses thrive, and the pastures become more balanced.
2. Phosphatic fertiliser greatly increases both the quantity and quality of feed.
3. Sheep mature earlier on top-dressed natural pasture, and earlier still on well fertilised sown clover and Wimmera Rye Grass pasture.
4. Sheep maintain 20 per cent. better development on clover and Rye Grass pasture.
5. Lambing percentages have averaged $19\frac{1}{2}$ per cent. greater on these pastures.
6. Wool production has been $12\frac{1}{2}$ per cent. greater per head on sown pasture than on top-dressed natural pasture, and $16\frac{1}{2}$ per cent. greater than on unimproved land.
7. Continued applications of 90lbs. 45 per cent. superphosphate per acre per annum have proved the most economic phosphatic fertiliser dressing, increasing carrying capacity 200 per cent. over period of nine seasons.
8. Superphosphate has increased the wool production from 8lbs. 14ozs. per acre on unmanured pasture to 39lbs. 2ozs. per acre on clover and rye pasture.
9. Lime with superphosphate has further slightly increased the carrying capacity, and causes more growth in the colder months of the year, and has increased the wool production a further 6lbs. per acre.
10. Rock Phosphate has increased carrying capacity 120 and 140 per cent.
11. Ephos Phosphate has increased carrying capacity 130 and 170 per cent.
12. Potash has increased carrying capacity 37 per cent.
13. Artificial Nitrogen fertiliser has increased carrying capacity 17 per cent., and caused slightly more winter growth.
14. *Phalaris tuberosa* is proving a most persistent and prolific perennial grass.
15. Perennial Rye Grass gives quick response to summer and autumn rains, but fails somewhat in winter feed.
16. Subterranean Clover pastures, provided they are well fertilised and managed correctly, are not improved by breaking and cropping the land at short intervals.
17. On Subterranean Clover and Wimmera Rye Grass pastures the average loss of sheep for three seasons has been 4.86 per cent.
18. On improved natural pasture the average loss of sheep for four seasons has been 0.82 per cent.
19. Pastures benefit by mowing, and the average yield of meadow hay over six seasons has been 1 ton 16cwts. 78lbs. per acre.
20. Improved clover pastures are proving suitable for dairying.

THE MEAT EXPORT TRADE.

(An Address delivered by MR. H. J. COPLEY, Chairman Stock Salesmen's Association, at the 44th Congress of the Agricultural Bureau, September, 1933.)

COMMENCEMENT AND DEVELOPMENT.

The meat export trade of Australia has been carried on in the past with varying success. The principal outlet has always been the markets of Great Britain, and the enterprise has had to meet strong competition and often superior organisation. The building up of a large stable and permanent trade has been the desire for many years.

The primary cause of the retarding of the progress hoped for has been the lack of proper organisation so essential to the success of a great undertaking of this nature. However, there is now an opportunity presented to the Commonwealth to establish a permanent and extensive industry with Great Britain on lines which have not previously been possible.

Export of meat has been carried on by many countries for a long time past, and as we all know, it is no new idea. We can go back to the days of the great Francis Bacon, who had a prophetic glimpse of what the chilling of foodstuff might do to make human life more agreeable. His fatal illness in 1626 was brought on by stuffing a fowl with snow to see how long decay could be prevented.

But it is only just more than half a century ago that large scale refrigeration made it possible to bring over the first cargo of frozen meat from the Antipodes to Great Britain.

Much progress has been made in the carrying of meat overseas, and science has come to the rescue with an astonishing degree of success which is opening up a new era for Australia's meat export trade. In addition to this we have other great factors which ally themselves to make up the opportunity which is now presented to this country.

OTTAWA AGREEMENT.

There has been an ever-increasing movement fostered to increase trade within the Empire, and this great thought has been crystallised by the Ottawa Agreement, whereby it was agreed between the delegates from Great Britain and the Dominions to restrict the imports of foreign meat into Great Britain, and at the same time to give preference to Empire meat on the quota system and allow for reciprocity in trade within the Empire generally. The opportunity came with the meat glut last year in the English market, which was the climax.

The quota allowed to Australia is admittedly liberal, and England to-day is scrupulously fulfilling her undertakings, and the obligation is now upon Australia to do her part.

Up to June 30th, 1933, 1,713,523 carcasses have gone, with 2,586,477 still to be sent if available. The quota for 1933 is 4,300,000 carcasses of mutton and lamb, which would be the highest ever shipped, but it is very unlikely that this total will be reached. This is not vital, as it must be borne in mind that the quota system was introduced to assist home-killed meat in England, and if we are short in delivery it will benefit the British producer, which is one of the objects. After June 30th, 1934, there will be no quota so far as Australia is concerned—we can ship all we produce. It can be safely assumed that from now on the Agreement will be a great help to Australian stock values. The progressive restrictions upon foreign imports are now becoming effective. These are as follows:—

	Per cent.
For quarter ending March, 1933	10
For quarter ending June, 1933	15
For quarter ending September, 1933	20
For quarter ending December, 1933	25
For quarter ending March, 1934	30
For quarter ending June, 1934	35

Are we going to respond to the invitation and seize the opportunity offered us in a reciprocal spirit? For I say definitely "that a tariff that does not foster the true spirit of reciprocity is uneconomic and will not succeed."

It is acknowledged that our efforts can be centred almost wholly in this market. Great Britain has to import half the meat which is consumed. Practically none of it could reach there if it were not for cold storage. It is for this reason that Britain leads the world in refrigeration research. The consuming power of Great Britain can be gathered from the following figures, which show the amount of meat used (per annum):—

An examination of these figures shows that England produces more than 50 per cent. of the total. On the other hand, some extent of the market can be estimated from the foregoing.

An effective organisation in Australia is essential for success and the appointment of a Commonwealth Meat Export Board is imperative. The personnel should be selected from those directly interested in all spheres of the industry and should be conducted independent of political control.

(c) Levy on export carcasses for publicity purposes.

Whilst the Crossbred ewe mated to British breed rams is ideal, it is recognised that sufficient numbers of the former are not available in this State, and the substitution of large-frame station Merino ewes is the only course. These should be carefully selected for the purpose. When exporting, all Merino lambs should be placed in a separate class to British breeds.

The market to-day shows a preference for light-weight lamb, which is the reverse of a few years ago when the heavy class was in favor. That we can produce the types is beyond doubt. The lambs shipped in 1932 were the finest ever sent by any country to Great Britain from this State.

PORK.

There is undoubtedly a large field for development in the export of pork, and growers are strongly urged to take active steps to enter this trade, but it is necessary to follow closely the requirements of the English market. The advice given by the Trade Commissioner in a letter dated July 27th gives a constructive criticism on the recent consignment to England. The comments, if closely studied, convey very valuable advice to growers. It will be noted that the heavy fat pig is not wanted. Breeders must get down to a type as in the lamb trade and carefully watch conformation, which is so necessary.

The pork trade is a business which can be maintained continuously throughout the year, and the objective of growers should be to accomplish that task.

COOPER CUP.

Retailers in Great Britain are showing willingness and enterprise to assist in developing trade with Australia. The practical example by Mr. Cooper, of Portsmouth, who has presented a Cup to Australian producers, and has further shown his sincerity by offering to give distinct preference to Australian meat, is highly commendable, and we owe a debt of gratitude to Mr. Cooper for such assistance.

MUTTON.

Possibilities for mutton export trade are improving, and it is hoped this may be possible before long. An outlet would improve future prices and leave behind the unpayable values which have been ruling.

BEEF.

Frozen beef is now a thing of the past, and it is necessary to concentrate on the export of the chilled product to obtain a share of the trade.

The possibilities in this direction are showing great promise in the light of experimental shipments which have been made, and so far given very encouraging results. Chilled beef is the only avenue through which success will be obtained. The experimental results of well-known meat firms have established the fact that the export of chilled meat is possible. Shipping companies have willingly given every assistance by making the necessary provisions to enable the carriage of the cargoes.

Credit for this important development is largely due to the efforts of the Cambridge Research Institute who have led the way in providing the methods of preservation by use of carbon-dioxide, a gas that prohibits growth of moulds on the beef. Moulds cause decomposition, which has been the difficulty in the past.

Australia would be well advised to turn attention to the class of beef required, and growers have an urgent and important duty to perform in supplying the requirements of the trade, which is the breeding of young steers of good quality representing a dressed weight of 650lbs. to 725lbs. at the age of 2½ years.

EXPORT SEASON, 1933.

The 1933 season has opened with much improved prices for growers, and at present is one of the most profitable lines. Prices, compared with last year, have doubled, and there appears to be no reason why values should not remain payable, thus giving justification for full development of lamb production in the rainfall areas.

In order to establish a definite trade we must persevere in spite of variation of prices in the overseas market. By doing so our meat products will establish a reputation and ensure the market on merit. It has been the policy of the Meat Export Board to pursue this course, and we feel there is ground for encouragement in the progress which growers have made in developing the type of carcass. This reflects credit upon producers for the manner in which the enterprise has been taken in hand.

HANDLING LAMBS.

A word of warning in regard to the handling of lambs I feel is urgent. Bruising has been all too prevalent, and it is impressed upon owners that rejection is actually the owners' loss, as the buyer must make allowance when purchasing. Whilst there are many causes, such as wool pulls, sticks, and dog bites, I would stress the dangers of road transport unless the motor conveyance is carefully driven to avoid surging. Construction of the carriage is also important. From the experience of the Meat Board this year we are convinced that the motor lorry is a serious offender in cases of vehicles not properly constructed.

THE STATE'S FLOCK.

State's Flocks and Where Grazed.

Division.	Sheep. Year 1932.
Central	1,501,929
Lower North	1,232,763
Upper North	1,005,608
South-Eastern	1,306,586
Western	935,778
Murray Mallee	558,074
Total Counties	6,540,738
Outside Counties	1,172,498
Total State	7,713,236
Increase	1,104,255

This year constitutes a record for sheep, the figures being 7,713,236, and it will be noted that there are outside Goyder's Line 2,909,508 sheep, whilst inside the numbers total 4,803,728. This shows the carrying capacity of the inner areas, due allowance being made for cultivation at the same time. Some idea of the possibilities of the lamb trade can be gained from these figures. The outside areas, of course, will always remain for wool production.

FINAL.

I feel that, with aid of top-dressing for the development of pastures in the rainfall areas, our meat export industry is only in its infancy, and there is a great field for development. That the market is available has already been stressed heretofore, and it now rests upon ourselves to make a success of the enterprise which is within our grasp. The opportunities of this trade must not be overlooked, for in this section of the industry there is offering one of the most profitable avenues for producers.

THE STATE'S EQUIPMENT.

There is available to producers a complete organisation to render any assistance or advice in connection with meat production for the export trade.

PASTURES.

The Waite Research Institute is always ready to give its valuable knowledge on the production of the most suitable pastures. In the Agricultural Department we have a well-equipped organisation, with competent officers, who are in direct touch with the producers on all matters. The Agricultural Instructors are posted in all divisions throughout the State.

The Produce Department will always give information through the Trade Commissioner in London in regard to the market there. It will therefore be seen that all information is available, and it is up to us to "deliver the goods."

The co-operation and effort of everyone interested is most strongly urged.

SALIENT POINTS IN THE PRESERVATION OF FRUIT.

(Paper read by MR. E. F. WARD (*Stanley Flat*) at the 44th Congress of the Agricultural Bureau, September, 1933.)

The problem of storing produce for a period between the time it leaves the hands of the producer and the time it reaches the consumer occupies to-day a pivotal position in the general economy of the world's food supplies. This fact is well illustrated in the case of fresh fruit and vegetables. The great developments which the last half century has witnessed have largely depended upon progress in the efficiency of cool storage and transport. The changes which are taking place in the organisation of the industry may be summarised as follows:—

- (1) The location of mass production, without regard to centres of population, whenever the best conditions of climate, soil, and labor are to be found.
- (2) Concerted action in the marketing of produce aiming at the adjustment of supplies to foster a steady demand.
- (3) An increase in the variety of supplies available on all markets at all seasons.
- (4) The adoption of uniform grading and the use of standard packages, tending to create standard products.

These changes, which make for increased efficiency, depend directly or indirectly on our ability to preserve perishable food products out of season in good condition for periods sufficient at least to allow of their transport over long distances.

COOL STORAGE.

The object of cool storage as applied to fresh fruit is to retard the life processes which continue after the fruit is picked, and so by lengthening the life of the fruit extend its marketing period. Research work in fruit cool storage may be divided into two parts—the first dealing with the way in which pre-storage factors affect the subsequent behavior of the stored fruit, the second dealing with the actual life processes of the stored fruit and how these are affected by the cold storage conditions of temperature, humidity, and atmospheric composition. Pre-storage factors affecting the subsequent keeping quality are numerous.

Firstly, there is climate to be considered. G. B. Tindale, B.Sc., Melbourne, states:—"We have made the general observation over several seasons that William pears grown in the warm Goulburn Valley keep much longer than the same variety of pear grown in the cooler southern districts."

I. S. Calwell has conducted in the United States of America an elaborate test on various fruits to test the effect of climate on the keeping quality, and has found that in years of most sunshine the greatest quantity of sugar is stored in the fruit, and the fruit stores longest.

Orchard operations such as cultivation, manuring, irrigation, and pruning all have a decided influence on the size and texture of the apple. Over-sized, soft-textured fruits do not store well, and cultural activities should be directed towards producing firm-fleshed, medium-sized fruits.

Dr. Barker, of the Cambridge Research Station in England, who has examined several shipments of Australian fruits shipped to London, says:—"There is a markedly greater wastage among the large-sized apples," and he raises the question whether it would not be better to restrict the export of large-sized apples. I take it that he means 2½ in. to 2¾ in., which is the most popular size demanded by overseas buyers.

IRRIGATION AND RAINFALL.

With regard to irrigation there is evidence that late watering causes apples to break down rapidly in cool store. Tests were made in Victoria at Ringwood with Jonathan apples so well known in this State. The apples were picked at

weekly intervals; owing to dry weather, the first two pickings resulted in very small apples. Between the second and third pickings bounteous rain fell. The apples filled out rapidly, the next pickings being of very large sizes. It was found that the fruit gathered after the rain—especially the final picking—suffered from breakdown and fungal rots, while the former pickings kept excellently.

PHYSICAL DAMAGE.

I cannot stress too greatly the necessity for careful handling of fruit in all the processes through which it passes from orchard to consumer. This fact should be so apparent that it should not require mentioning. Unfortunately, however, the largest share in the wastage of fruit through cool storage at the present time may be traced directly or indirectly to rough handling.

Damage to the skin during picking, packing, and transport causes juices to ooze out, and these provide an excellent medium for the development of fungal rots. It is scarcely too much to say that almost all fungal attack commences on abrasions on the skin of the fruit. It is, therefore, impossible to over stress the necessity for treating *all fruit* as it really is, a *very fragile commodity*, and to handle it with such care that it enters into its period of senescence in the best condition possible, and not partially maimed and open to attack by disease before it even enters into its storage period.

CORRECT TIME AND MATURITY FOR PICKING.

"One of the most important pre-storage factors," says R. C. Palmer, of the Summerland Experimental Station, British Columbia, Canada, "which influence the subsequent storage life is the correct stage of maturity at the time of picking." Undoubtedly there is a correct time to pick fruit for storage. In the course of the preparation of this article I found much literature on this subject, and will later give the general verdict on this matter.

Apples picked too green shrivel and lack size and quality. Apples left on the trees too long become soft, and subsequently suffer from breakdown in store. They should therefore be picked at an intermediate stage of maturity. As fruits vary from year to year in their time of ripening, it is not possible to specify the best date or month for gathering.

The color of the unblushed side of the apple forms a reliable guide. As the apple ripens the color on the side of the fruit changes from a green, through a green-yellow, to a yellow. The fruit should be picked when the unblushed side is green-yellow. The most general verdict comes from R. C. Palmer, whose name has been mentioned earlier. He says:—"I have carried out tests extending over several seasons with Jonathans, picking them at three stages of maturity,

FRIENDLY SERVICE ALL THE TIME.

Some of the time, if not all the time, you must save money, but if you are Mr. Average Citizen you know that **ALL** the time is nearer the mark.

Whatever your margin on any one week's salary, it won't provide for a sudden necessity to pay, say, £50 or £100. No one week's salary will provide education for your children, heavy medical expenses, or comfort in your declining years.

Therefore, to make provision for the big calls, you **HAVE** to save, more or less, **ALL** the time.

The Commonwealth Savings Bank provides a friendly efficient savings service—**ALL** the time.

Commonwealth Savings Bank of Australia

GUARANTEED BY THE COMMONWEALTH GOVERNMENT.

i.e.—(1) When the unblushed side is green; (2) green-yellow; (3) yellow. My experiments have definitely proved that where Jonathans were left on the tree too long—*i.e.*, when the unblushed side had turned yellow—the percentage of breakdown was very high. By picking the apples at the intermediate stage of maturity the apples were of good quality, average size, and suffered little from subsequent breakdown.”

In order that orchardists may readily recognise the correct stage of maturity for picking Jonathans, Mr. Palmer has devised a very simple color chart. On it are pasted the three colors, each color being perforated by a large hole. By placing the apple against the hole the color can then be very quickly matched. Mr. Palmer's system of testing the stage of ripeness for apples by color card is very widely used in Western Australia, Victoria, and Tasmania, the biggest centres of export of this fruit in Australia. Those States are in exact agreement with Mr. Palmer's results, and orchardists are advised to give the matter of maturity at picking time much consideration.

For the iodine test for ripeness obtain commercial iodine and dilute to 2 parts iodine to 1 part water, or $66\frac{2}{3}$ per cent. iodine and $33\frac{1}{3}$ per cent. water, and place in a saucer. Immediately after cutting the apple or pear dip smartly in the solution. When the fruit is immersed the sugar shows out white and the starch dark. When black and white blotches appear evenly spread over the whole surface of the cut portion the fruit is ready to pick. If even blotches are only to be found just around the core or around the circumference the fruit is just as well left on the tree until a uniform test is obtained. The iodine test is very unreliable and practically out of use, because it has been found that with the green or hard variety of apples such as Cleopatra, Granny Smith, Dunn's Seedling, and Stone Pippin all test very well and form a reliable guide as to maturity, whereas the colored or soft varieties—Rome Beauty, Jonathan, Scarlet Pippin, and others—on account of their softness cannot be tested very reliably by this method. Varieties of pears differ in that respect also.

STORAGE PERIOD OF FRUIT.

Research workers are investigating the life processes which continue after the fruit is picked, and how the storage conditions of temperature, humidity, and composition of the atmosphere affect these processes.

When the fruit is stored it continues to take in oxygen and give off approximately equal quantities of carbon dioxide. At the same time the sugars, starch and acids which were formed while the fruit was growing are gradually used up, heat being evolved in the process. When these supplies are exhausted rot and decay set in, and the fruit is no longer fit for human consumption. By measuring the rate of production of carbon dioxide one obtains a measure of the rate of living of the fruit.

This line of research has been carried out by the Low Temperature Research Station, Cambridge, with results of great practical and scientific value. It was found that with the apple the respiratory activity steadily increased after being placed in store. In one case with apples stored at 54° Fahr. there was a steady increase in respiratory activity for 25 days, after which the activity greatly diminished. At the point of greatest activity—called the climateric—it was found that flavor and aroma were developed to a maximum. After the climateric is reached, *i.e.*, when the respiratory activity slows down—that is, when the sugars, starch, and acids are almost exhausted—the apple is definitely on the down grade, and quality suffers. The apple becomes mealy, and the flavor poor. Just before the death of the fruit the respiratory activity slightly increases, then the production of carbon dioxide ceases; the apple then ceases to live. It is found that even though the apple be dead there still remain some sugars and acids.

It may be of interest to growers to know just how long fruit may be kept in cold or air storage. The following varieties of pears may be kept for the following periods:—

Varieties.	Days.
Williams's Ben Chretien	30—40
Williams' Bartlett	30—40
Howell	90—120
Beurre Bosc	90—120
L'Inconnue	100—110
Winter Pear (Nelis)	180—210

APPLES.

Varieties.	Days.
Jonathan	100—130
Dunn's Seedling	150—180
Rome Beauty	110—130
Stirling Castle	90—120
Lane's Prince Albert	190—210
Cleopatra	90—110
Peaches of the yellow flesh variety	14
Peaches of the white flesh variety	21
Tomatoes	14

Plums are not kept in cool store for export from this State. South Africa supplies most overseas demands, and the following varieties exported from that country may be kept as follows:—

Varieties.	Days.
Coe's Golden Drop	35
White Washington	21
Japanese Plums (usually)	21

Quinces can usually be kept from 6—8 weeks.

The storage life of plums, peaches, and grapes is, in general, much shorter than that of pears and apples, and for this reason their transport over the longer distances presents serious difficulties. Thus while these fruits are now imported with considerable success from South Africa to England and Canada—a voyage of about three weeks—the journey of five to six weeks from Australia to England is but rarely attempted with peaches and plums, and in the case of most varieties of grapes it is attended with uncertainty. With regard to wastage of the various varieties of plums, peaches, and grapes in cool store, the literature examined afforded me surprisingly little information of the nature I required, and of the best conditions for their storage. My description, therefore, will be largely confined to the types of wastage commonly found in apples and pears exported under cool storage.

WASTAGE DISEASES.

There are several physiological disorders of the apple occurring while still on the tree, and others which are only revealed by a period in cool store. Of the disorders which occur while still unpicked there is the well-known disease "bitter pit."

This, I might say, is one of the most serious disorders occurring in Australian apples. The trouble first develops in the orchard, but becomes more obvious and commercially more disastrous during the storage life of the affected fruit, although there appears to be no evidence of its appearance in the case of fruit quite sound when gathered from the tree.

The flesh of the affected apples shows small masses of brown, spongy tissue, usually confined to the outer part just under the skin. Sometimes more deep-seated tissues are affected, and when, by coalescence of several small masses or otherwise a moderately large patch of brown tissue is produced in the heart of the fruit, the appearance simulates that of Brown Heart to some extent.

Hollow Core is another disease which forms while the fruit is yet on the tree. It is found almost exclusively in the Cleopatra, and is termed an abnormality, brought about by the splitting of the top of the capillary chamber and the extension of this split through the flesh of the apple, sometimes almost to the skin. The tissue lining this cavity becomes brown and woody, and the interior of the apple in extreme cases assumes a most unsightly appearance in consequence, although externally a misshapeness is the only sign of this abnormality. The condition is seldom met with, however, in this advanced form.

There are several other disorders which may be noticed on fruit unpicked, namely, "scald," which is marked by the browning of the skin on one side of the apple. Fruit suffering from sunburn and *Fusicladium* should be discarded before storage and export.

STORAGE DISEASES.

A condition of the fruit known as Internal Breakdown is the most commonly met with. It is a storage trouble associated with the senility of the apple, and is the typical cause of wastage of fruit stored for over-long periods at low temperatures. It is normally characterised by a vague browning of the outer part of the flesh.

Core Flush and Flesh Collapse are names given to similar browning noticed in the core region, which occurs in storage under similar conditions.

Brown Heart.—In apples affected by Brown Heart a ring of browned tissue is often present midway between the core and the skin. In mild cases the browning may be restricted to isolated areas in the flesh, while in severe cases the whole of the flesh may be brown. The sharp definition of the brown flesh from the healthy tissue is especially characteristic of the disease. Brown Heart caused disastrous losses in the Australian apple trade in 1922, entire shipments arriving in an almost valueless condition. The cause of this disease is said to be inadequate ventilation of the ship's holds, and the added accumulation of carbon dioxide during the voyage allows this condition to take its toll.

Jonathan Spot is chiefly confined, as its name suggests, to the Jonathan variety. It is characterised by black or brown spots in the skin of the fruit. It is extensively found in Western Australian apples of this variety. No reliable methods of control have as yet been established for the storage diseases mentioned.

Fungal Rots, as the name implies, refer to the fungus variety of spores which set up and bring about rotting of fruit. The rotting is caused by the germination and growth of fungal spores on the surface of the skin or, occasionally, in the cavity of the core; the affected tissue becomes soft and discolored, and is often water-soaked and clearly delimited from the sound flesh.

Since the fungus usually spreads through the tissues at roughly the same rate in all directions, the shape of the lesions is a useful criterion for distinguishing between fungal rotting and the breakdown due to various physiological diseases.

Fungal rotting is seldom extensive in fruit at the markets which receive exported fruit, but observation has shown that fruit which is fairly mature on arrival may be seriously affected during marketing and distribution. The information with regard to wastage and diseases occurring in fruit in cool store are extracts from articles written by J. Barker, M.A., Ph.D., who is conducting experiments at the Research Station, Cambridge, and the Covent Garden Laboratory, London.

The assistance rendered by the Department of Agriculture in placing the literature referred to at my disposal is gratefully acknowledged.

EGG PRODUCTION ON THE FARM.

(Paper read by Mr. F. WORMALD (Gawler River) at the 44th Congress of the Agricultural Bureau, September, 1933.)

Do fowls on a purely egg production basis pay the man on the land living away from the metropolitan area, who has to depend almost solely on egg production for all his income from poultry? I have established this side line on my farm and am of opinion that if one has the patience and capital there is more profit in fowls than cows if one has to depend solely on the cream cheques for profits. Selling milk, of course, is a different matter. To start off it is necessary to decide whether it is cheaper to buy day-old chicks or purchase an incubator and hatch them. Unless one has good fowls worth breeding from, it would be the wisest plan to purchase say 200 from a reputable breeder of well bred stock. Obtain stock from proved good layers; if it is intended to hatch on the farm, then secure a good laying pen of say, six hens and a rooster. One sound argument in favor of breeding your own chicks is that you know what size eggs go in the machine.

INCUBATION.

I prefer a 2½oz. egg for incubation, and certainly nothing under 2ozs. Also see that they are not rough shelled, mis-shapen, or ridged. If the eggs are dirty they should be washed, this does not harm the egg. The pores of a dirty egg are blocked, and this will prevent a good hatch. Be very particular about the freshness of the egg; if it is over six days old reject it. It is a good plan to turn the eggs at least once a day, preferably twice a day; this prevents the embryo from sticking to the shell. Before placing the eggs in the incubator see that it is properly regulated to obtain a regular heat of 103° for about 24 hours.

Manufactured by

Wallaroo-Mount Lyell Fertilisers Limited,

AT PORT ADELAIDE AND WALLAROO.

When the eggs are put in the temperature will drop considerably; it will again rise to 103° if the machine is working properly. If the machine is not fitted with automatic egg turners, it is a good plan to mark one side of the egg with a red pencil and on the opposite side mark with blue pencil; this simplifies matters when turning the egg. Never use an indelible pencil. Clean the lamp every day, so that it will not smoke; the latter is fatal to chicks.

TESTING EGGS.

Do not turn the eggs until they have been in the machine for 48 hours. On the seventh day they should be tested to ascertain if they are fertile or not; if in doubt about some of the eggs, allow them to remain and test again on the tenth day. To make a simple tester, procure a piece of cardboard or tin about 8 in. square; in the centre cut a hole the shape of an egg, but not quite so large, otherwise the egg will slip through it. By passing this over an electric light or before a bright lamp, one can easily see the embryo. It is not unlike a spider with a black spot about the size of a sweet pea seed. Eggs that show a streak of blood running around the egg must be rejected; this is a broken yolk. When turning the eggs for the first few times, only leave them out of the incubator as long as it takes to turn the eggs; the second week they may be left out longer, and the third week for 15 to 20 minutes. At all times take into consideration the weather, and do not chill the eggs. Do not turn eggs after the eighteenth day. Always see that the bulb of the thermometer hangs or rests on a level with the top of the eggs and over a fertile egg.

MOISTURE.

This is an important, yet complex, question. In incubation, if there is too much ventilation, and if the atmosphere is too dry, there will be excessive loss of moisture from the eggs. The various constituents of the egg are intimately associated with water. The growth of the embryo depends upon a definite proportion of water at all times of incubation. The egg contains on an average 70 per cent. of water, held in chemical and mechanical combination, and is in the egg to that amount for very definite purposes. The carbon dioxide and water given off by the embryo are associated with the important work of slowly altering the structure and composition of the shell. The action of the respired carbon dioxide and moisture on the carbonate and phosphate of lime in the shell results in dissolution, and finally a brittle, easily fractured shell, from which the chick easily emerges. Watch the air space in the egg; if it is too small this indicates that the chick is developing too quickly by the presence of too much moisture; on the other hand, if the air space is very large, this indicates that the chick is not developing sufficiently because there is not enough moisture in the incubator. When the chicks are chipping the eggs, do not open the door of the incubator, because the cold air entering the machine may chill the eggs and prevent a good hatch.

BROODING.

When removing the chicks from the incubator room to the brooder house, protect them from any wind; they easily catch a chill and much loss from bowel troubles is due to this. Brooders are made in many styles, both heated and unheated. The general practice, when chicks are hatched in winter or early spring, is to house them under a heated brooder for about three weeks, then transfer them to a cold brooder; be very careful not to overcrowd the chicks at all times. A brooder that will hold 100 chicks at birth cannot be expected to hold them in three weeks' time, because as the chicks grow they require more room and more fresh air, but not draughts. See that the chicks do not crowd in corners; the corners must be rounded off with tin or preferably wire netting and then the chicks are not likely to trample one another to death. Watch them in the evening when they are going under the brooder because some of the chicks crowd in the corners.

FEEDING CHICKS.

Dry mash for two weeks at least is the general rule and bran three parts and pollard one, with about 6 to 8 per cent. of dried buttermilk powder, is good. I also have cracked wheat, maize, and peas in containers. See that the chicks cannot get into these, otherwise they scratch out the grain on to the floor, and much is wasted. Also always have finely crushed charcoal in the food, enough to turn the bran and pollard a greyish color; shell grit also should be provided. After a couple of weeks, finely chaffed green feed may be fed, but it must be fresh; avoid stemmy feed, such as old lucerne; fowls cannot digest fibre. Lettuce, rape, and silver beet are ideal chick green feeds. Do not use spices or nostrums. Sunlight and good food with plenty of greenstuff will result in good, strong, healthy chicks.

REARING PULLETS.

As the chicks are growing keep an eye open for the cockerels and separate them from the pullets at once. When they are about six weeks old and the weather is good they may be transferred to portable or larger sheds out in the open and allowed free range. This method saves a lot of food, because they practically live on grass, &c., but always have food for them if they wish to partake of it. Always provide clean drinking water; this should have a wire guard over it to prevent the chicks falling into it. After a couple of months, feed the same way as is intended when they are laying. By this means they do not get a setback or go into a false moult after laying a few eggs. The principle is to so feed pullets coming on to lay that they may have a good reserve stored up; if they have not this reserve, they lay a few eggs then go into a moult.

FEEDING FOWLS FOR EGG PRODUCTION.

When the pullets are put into their permanent quarters, which must face north or north-east to allow the maximum amount of sunlight to shine into the sheds in the winter, reckon out the number of birds a house will accommodate. This is ascertained by multiplying the length by the depth in feet and dividing by 3; thus a shed $12 \times 10 = 120$, divided by $3 = 40$ fowls will be its capacity. The floor should be covered with cocky chaff or short straw 4in. to 6in. deep to make the birds scratch for their grain. Some prefer loose dirt or sand for litter; in either case they should always have a dust bath provided. The dust allows the birds to rid themselves of any vermin, and during the moult, the casting of old feathers, and the growth of new plumage will be assisted. Charcoal and shell grit should always be available for the birds to help themselves. By using kerosene tins for nests and half filling these with shell grit, the eggs will be kept clean, and the birds will help themselves whilst sitting on the nest. There are two methods in common use—(1) wet mash and grain, (2) dry mash and grain. In both methods, green food should be used freely and plenty of clean water always available.

WET MASH.

The usual practice is to give this in the morning, followed by green feed alone at midday and grain in the evening. See that when the grain is fed it is covered by the litter to make the birds scratch for it, and at daylight the birds are at work again. The good layers are out first in the morning and are the last to go to the roost at night. A good mixture is bran one part by measure, pollard two parts by measure, chaffed green feed five parts by measure. Scald the bran with hot soup made of meat meal, allowing $\frac{1}{2}$ lb. to each 100 adult birds and 1oz. of salt. Allow this to soak and swell. The scalding is to provide heat to burst the starch grains; cold water will not do this, the hot water starts the process of digestion. Whilst hot add green feed and dry off with pollard. Mix it well until it is rather dry and flaky. The daily allowance is $\frac{3}{4}$ oz. of bran and 1oz. of pollard per bird. On no account throw this food on the ground; feed it in food troughs, thoroughly clean, and to prevent the birds from stepping in it or scratching it out on to the ground, fix some pieces of fencing wire across the top

of the troughs. At midday give them as much green food as they will clean up. This must be palatable. About an hour before sundown throw their grain to them, allowing about 1½ozs. to 2ozs. per bird—wheat for preference.

DRY MASH.

Dry mash is fed in hoppers and the method is certainly saving in labor. I have adopted both methods of feeding, and claim just as good egg production as from wet mash. As fowls cannot swallow dry mash until it is moistened by saliva, this is a great point in favor of this method. My practice for mixing the dry mash is equal parts by measure (not weight) of bran and pollard, 10 per cent. meat meal, with one handful of charcoal to a kerosene bucketful of the above. I leave the feed hoppers open until 2 p.m.; then they are closed, but green food is supplied twice a day. An abundance of green feed means the cutting down of costs of other foods, and green feed is the cheapest. It is surprising what a lot of it they will eat if it is succulent; it also supplies invaluable mineral salts, in the absence of which no stock can thrive for any length of time. Fowls are like other producing animals on the farm; you will only get out of them according to how you feed them, *i.e.*, it is only the rich man that can afford to starve his stock.

GUIDE TO PICK THE BEST PRESENT PRODUCERS.

Laying Hen.

Vent, large, dilated oblong.
Pubic bones, flexible, wide apart.
Comb, large, red, full, glossy.
Wattles and lobes, prominent, smooth, soft.

Non-Laying Hen.

Vent, small, contracted.
Pubic bones, rigid, close.
Comb, small, pale, scaly.
Wattles and lobes, inconspicuous, rough, dry.

HOW TO JUDGE PAST PRODUCTION.

Long Period Laying Hen.

Vent, bluest white.
Eye, thin white.
Ear lobes, pearly white.
Beak, pearly white.
Shanks, white, flat, round.
Plumage, worn, soiled, lifeless.

Short Period Laying Hen.

Vent, flesh colored.
Eye, thick yellow.
Ear lobes, yellow, tinted.
Beak, yellow tinted.
Shanks, yellow, round.
Plumage, signs of moulting, loose feathered.

A FEW COMMON COMPLAINTS IN POULTRY.

The most common is tick fever. Prevention is the only cure. The tick is a fowl parasite, and if the birds are allowed to go anywhere on the farm to roost, the tick will be there with them. If the birds are properly housed or only shut up at night, then tick is easily controlled by flooding the joints, all crevices and cracks in the timbers, and especially the perches, with old oil and kerosene in the proportions of two to one; the perches should be movable. Symptoms of tick fever are easily detected—loss of leg power, manure of a greenish color, and wings drooping. Feed lightly on soaked bread and milk; mix one teaspoonful of ginger, one teaspoonful of Epsom salts, one pint of boiling water, and when cold, bottle, and give birds one teaspoonful twice a day. Birds that recover from tick fever never contract it again.

Chicken-Pox is easily cured if close watch is kept on the flock, and affected birds picked out early. Pen them off, as it is very infectious, and paint sores with a small stencilled brush dipped in iodine.

Soft-shelled eggs are generally due to overfeeding, also lack of lime, salts, etc.; see that such birds have plenty of shell grit.

Wheat is now about 8s. to 9s. per bag, bran and pollard £5 2s. 6d. per ton. Whilst these prices rule, I find it costs about 1d. per week to feed each bird, and on the average farm eggs can be produced for 4d. per dozen; this is reckoning on food only, not housing and chick raising.

TWO DISEASES OF SHEEP OF ECONOMIC IMPORTANCE IN SOUTH AUSTRALIA.

(Paper read at the 44th Congress of the Agricultural Bureau, September, 1933.)

[By C. T. McKenna, B.V.Sc., M.R.C.V.S., Government Veterinary Officer,
Stock and Brands Department.]

PARASITIC GASTRO-ENTERITIS OF SHEEP.

During the spring, summer, and autumn of the 1932-1933 season, reports were received from many areas of the State of a disease in lambs, the main features of which were failure to thrive, loss of condition and weakness, followed by heavy mortalities. Field investigations on many of the affected farms and the examination of material from a number of affected flocks have shown that the disease is due to a severe infestation with internal parasites.

The effects of parasitic invasion are well known to sheep owners in the high rainfall areas of South Australia, but during the season under review the losses were much heavier than usual, the disease was more widespread, and further appeared in parts of the State previously considered to be "clean."

Parasitic Gastro-Enteritis is probably the most serious disease of sheep in this State, not so much on account of the actual losses, but because affected sheep show loss of condition, fail to thrive, their fleece is under normal weight, and the wool is tender.

A good deal of experimental work has been done, mainly in New South Wales, by Clunies Ross and also by Seddon, Belschner, and Edgar, and a resumé of this and of our investigations locally should be of importance to sheep owners.

Some common names for the disease amongst sheepmen are "Coast Disease" (a term which not only includes parasitism, but other obscure diseases of sheep in coastal areas as well), "Stomach Worm Disease," and "Black Scour of Lambs."

THE PARASITES WHICH CAUSE IT.

Those which have been found on examination of the digestive canal contents are, briefly:—

(1) THE "HAIR WORMS".—There are several varieties of these, but by far the commonest and most important is the *Trichostrongyles*. These are fine hair-like worms a little over $\frac{1}{4}$ in. in length which are found in great numbers in the small bowel and to a lesser extent in the fourth stomach. Their presence is only demonstrated with difficulty, but the most likely place to find them in the small gut is from 3-15ft. from its junction with the last stomach.

(2) THE LARGE "STOMACH WORM" (*Haemonchus contortus*).—This parasite can easily be recognised in the stomach and sometimes in the first part of the small bowel on account of its comparatively large size ($\frac{3}{4}$ -1 $\frac{1}{4}$ in. long) and the red and white spiral markings of the larger worms.

(3) "TAPEWORMS" (*Moniezia expansa*).—The worm is white and flat in appearance and made up of numerous segments. It may attain a length of 15ft. or more. Tapeworms inhabit the small bowel, and as many as 10 or more may be found in a single lamb.

(4) WORMS OF THE CAECUM AND LARGE BOWEL.

The following points are emphasised:—

(a) The infestation is invariably a mixed one, but one variety usually predominates.

- (b) That parasitic gastro-enteritis is due mainly to "hair worms" (*Trichostrongyles*) and to a lesser extent to the "stomach worm" (*Haemonchus contortus*).
- (c) It would appear that *Trichostrongyles* are much more widely distributed in the State than the *Haemonchus*, and that the former can withstand the effects of dryness and cold better; it appears in drier areas and infests sheep earlier in the spring than the latter.
- (d) Tapeworms do not appear to cause many losses in sheep. They do, however, affect them. They are a common parasite of lambs in this State.
- (e) The large bowel worms are believed to be capable of causing serious effects.
- (f) The female "hair" and "stomach" worms lay eggs which are passed out in the faeces. The eggs hatch out in the paddocks and ultimately develop into larval forms which settle on the grass and so are taken in by the sheep when feeding.

HOW THEY AFFECT THE SHEEP.

The parasites must look to their host, the sheep, to sustain them, and they either obtain their nourishment by piercing the bowel wall and sucking the blood, or by ingestion of the food in the canal. Further, they wound and irritate the bowel wall and cause digestive disturbances.

When their great numbers is considered, it is evident that they must weaken the sheep. A count of the "hair worms" in one lamb showed that 30,000 were present, and if they were placed end to end they would stretch a distance of at least 200yds.

SEASONAL INFLUENCES BEARING ON THE INFESTATION.

It is common knowledge that the effects of parasitic infestation vary considerably in different years. The disease is much worse during some seasons than others, and in this State the 1932-1933 season was a bad one. The years 1930-1932 were good years, and as a consequence the growth of feed was good and the soil was kept damp for considerable spells. This was particularly so during 1932. Now it is just these conditions—moisture and warmth—which are suitable for the development of the parasites outside the sheep's body, and it is no wonder that sheep became infested in greater and greater numbers until during 1932-1933 a maximum of losses was experienced. This run of good years probably accounts for the appearance of the parasite in areas previously considered clean. During dry years the disease is much milder in its effects.

AGE AND CLASS OF SHEEP AFFECTED.

(a) The "hair worms" (*Trichostrongyles*) chiefly affect hoggets, especially from 5 to 12 months old. Weaners and even sucker lambs may show the disease, but it is not commonly seen in older sheep unless such sheep have not previously suffered from the trouble as hoggets. The history usually is that once the sheep are 12 to 18 months old they are not again affected. It would appear that with age, a natural resistance to this parasite is developed. The period of the year that it affects sheep extends from early spring through summer and autumn.

(b) The "stomach worm" (*Haemonchus contortus*) causes serious trouble in both lambs and grown sheep, the latter often severely. Generally speaking, it is a complaint of late spring, summer, and early autumn.

(c) Tapeworms affect young lambs mainly.

SYMPTOMS.

From what has been said it is evident that there are two types of Parasitic Gastro-Enteritis, and from now on they will be described as:—

(a) *Trichostrongylosis*—"Hair worm disease."

(b) *Haemonchosis*—"Stomach worm disease."

The symptoms of *Trichostrongylosis* are as follows:—

The history is that the owner is having trouble in his young sheep. Though they are on good pasture and apparently receiving ample nourishment, they are not doing well. They are lacking in size and general development. A *dark-colored diarrhoea is invariably present*. When driven they appear sluggish, and can easily be caught. As the disease progresses they lose weight and become emaciated. In one district which I visited practically 100 per cent. of the hoggets in the various flocks examined were affected; the average losses were about 30 per cent. (75 per cent. on one property), and it was estimated that at least 3,000 young sheep had died in the area. In other districts the losses have varied from 10 per cent. up to 33 per cent.

In flocks in which the disease is not so severe there are marked gradations in size, and a "tail" is developed, *i.e.*, a percentage of the sheep are markedly undersized and in poor condition. On examining the sheep it is found that in badly affected ones the body is emaciated, the skin is pale, and "pot belly" is present. When the sheep is turned up, fluid can be heard in the belly. In less severely affected sheep, the skin appears pink and the belly is not distended; the owner in these cases rarely suspects worms and considers it is "something to do with the feed."

Haemonchosis, on the other hand, is more rapidly fatal. Scouring is variable and is sometimes absent. Anaemia (paleness of the skin) is invariably present. The affected sheep show swellings under the jaw ("Bottlejaw") and distension of the belly ("Pot Belly").

POST-MORTEM EXAMINATION.

The outstanding feature is the extremely emaciated condition of the carcase. There is very little internal fat present. On opening up the belly cavity a considerable amount of watery fluid is seen there. This fluid may, however, be absent in early cases of *Trichostrongylosis*. Where *Haemonchii* are present they can easily be seen in the fourth or last stomach, where they are found mixed in the ingesta or attached to the lining wall of the organ. In the case of *Trichostrongyles*, preliminary examination of the stomach and intestines gives the idea that no parasites are present, and in order to demonstrate that they are there, it is necessary to carry out the following procedure. After slitting up the small bowel and drawing out the contents, scrape the material off the bowel lining at a point about 6ft. from the fourth stomach. Put the scraping on a clean piece of sheet glass, mix with a little water, and spread out. If a piece of light or dark paper is now put under the glass and the mass is examined in a good light with a magnifying glass, the "hair worms" can easily be seen.

In view of the difficulty of finding these worms and the importance of knowing what type of worm is responsible for the trouble, it is strongly recommended that material be forwarded to the Stock and Brands Department for examination. A sick sheep showing typical symptoms could be brought on sent for *post-mortem* examination; in the latter case it should be sent direct to the Bacteriological Department, Adelaide Hospital, and this Department should be advised.

If bowel contents are forwarded scrapings from small bowel and stomach walls, together with a little of the fluid contents should be put in a clean bottle and mixed with an equal quantity of 10 per cent. formalin (1oz. of formalin with enough water added to make $\frac{1}{2}$ pint, equal 10 per cent. solution). Full details of the symptoms observed and type of sheep affected should be forwarded at the same time.

FACTORS WHICH PREDISPOSE TO INFESTATION.

1. **THE CONDITION OF THE ANIMAL.**—This is an important factor in determining whether the parasites will gain the upper hand or not. If the nutrition of the sheep is good they may carry quite considerable numbers of parasites without showing ill effects. It is when the nutritive value of the pasture falls off that the worms start to increase and affect the sheep. In this respect it is important to note that the high luxuriant growth of pasture of good seasons is much lower in nutritive value than the short, leafy type, and is quite inadequate for the grazing requirements of weaners.

2. **AGE.**—Young sheep have not only to maintain themselves, but they also have to grow, so they require plenty of good nourishing feed. As is well known, they are very susceptible to checks, *e.g.*, if they are put on to poorer feed. For this reason, young sheep are more susceptible than older ones to invasion by parasites.

3. **WEANING.**—This tends to cause a check if good feed is not available.

4. **OVER-STOCKING.**—This limits the supply of nutrition and makes re-infestation of the flock with worm larvae much easier.

TREATMENT.

I.—MEDICINAL.

(a) *The treatment of Trichostrongylosis ("Hair worm" disease) by medicinal means is almost ineffective.* However, it does some good, as it has been found that, although the disease was not checked, treated sheep running on natural pasture gave a much better wool quality than untreated sheep. Again, worm infestation is a mixed one, and medicinal treatment is effective against "stomach worms" (*Haemonchus*) and tapeworms. For these reasons it should be persisted in. The following medicinal treatment is suggested:—

(1) Where the disease is diagnosed:—Drench all hoggets at once with the standard copper sulphate solution. Repeat this drench seven days later. Subsequently drench monthly with either the copper sulphate solution or the carbon tetrachloride mixture.

(2) In areas where the disease is known to exist:—Weaners should be drenched monthly from the beginning of September onwards with either of the above drenches (preferably copper sulphate solution). The first dose should be just before separation from the mothers.

(b) **STOMACH WORMS (*Haemonchus*).**—They can be effectively controlled by drenching with carbon tetrachloride mixture. Less effective than this mixture is the standard copper sulphate solution, but it has the advantage that it is cheaper, easily administered, and very safe. A plan of treatment is:—

(1) Drench all sheep during July.

(2) Drench all young sheep and lambing ewes in September.

(3) Drench young sheep and lambing ewes at monthly intervals from November to May.

(c) **TAPEWORMS.**—Standard copper sulphate solution is an effective drench. The carbon tetrachloride mixture does not remove them.

Standard Copper Sulphate Solution.

The solution is prepared as follows:—

Dissolve 8ozs. of bluestone in 3galls. of water, and of this give the following doses:—

	Ozs.
Adult sheep	2
Two tooth's	1½
Lambs, 6 to 12 months	1
Lambs, 3 to 6 months	½

**ADELAIDE ROPE & NAIL CO.
LIMITED.**

CROYDON, SOUTH AUSTRALIA.

SUPPLIES OBTAINABLE FROM ALL DISTRIBUTORS.

In preparing the solution use only hard, blue lumps of the drug, and discard all lumps which are white and powdery. Break up the large lumps, and dissolve in a little boiling water, then add cold water to make up 3galls. of solution in an enamel bucket. Do not use an iron vessel for the solution, as it will act on the metal and become less active. A small glass bottle with a hole filed in the side in such a position that when plunged in the solution it will fill up with the exact dose, is suitable for drenching.

Carbon Tetrachloride Mixture.

This consists of:—

	Parts.
Carbon tetrachloride	1
Liquid paraffin	4

The dose of the mixture is:—

	Cubic Centimetres.
Lambs	5
Adult sheep	10

The mixture is sold prepared for use in 1gall. tins, and this quantity is sufficient to dose 900 lambs or 450 adult sheep. The cost is approximately $\frac{1}{4}$ d. per dose for an adult sheep.

Reliable all metal dosing syringes fitted with a long, slightly curved nozzle and adjustable by a screw on the handle for doses of 5c.c. or 10c.c. are available. For large flocks a reliable automatic drenching gun is on the market.

Owing to the fact that carbon tetrachloride evaporates quickly only a small quantity at a time should be poured from the container into a suitable vessel. The container should be well shaken before pouring out, and kept tightly stoppered at all times.

Precautions to be Observed when Dosing with Carbon Tetrachloride.

(1) In certain rare instances the drug though absolutely safe for normal sheep in doses five and 10 times the size of that recommended may cause some mortality. The reason for this is obscure, but one factor known to influence the toxicity of the drug is mineral deficiency (calcium particularly) in the pasture.

(2) Again, sheep grazing on soursobs should not be dosed with carbon tetrachloride. Sheep grazing on this plant do suffer from a deficiency of available calcium (lime).

(3) A precaution to be observed is to try the effect of the drug on a small percentage of the sheep of different classes (ewes, lambs, &c.). If no ill effects are observed in two days the rest of the flock can be drenched.

Drenching.

Before the administration of either copper sulphate solution or carbon tetrachloride mixture, the sheep should be yarded overnight and dosed on the following morning before being allowed food and water. They may be allowed to feed as soon as treated. The sheep should be dosed standing, the head should be forced upwards and backwards, and the lower jaw should be left free. In the case of the tetrachloride mixture, the nozzle of the syringe should be inserted over the sheep's tongue, and the syringe emptied steadily.

II.—ADEQUATE NUTRITION.

As has been stated, medicinal treatment of "Hair-worm" disease is unsatisfactory. However, during trials with various drugs, it has been observed that young sheep infested with *Trichostrongyles* but not drenched showed improvement when given more nutritious feed and "nursed." It would appear that the provision

of good, nutritious feed and good animal husbandry will do more to control this serious disease of lambs than medicinal treatment. As regards "stomach worm" disease, improved nutrition should also go hand in hand with medicinal treatment.

PREVENTIVE MEASURES.

(1) **GOOD FEEDING.**—Weaners should be nursed and given the best feed available from the time they are weaned until they are at least 12 months old. More cultivation of some of the affected areas, the top dressing of suitable parts, and the planting of lucerne, &c., should be helpful. The sheep owner should plan ahead for the feeding of his young sheep right from the beginning of the worm season (September to May).

(2) **SUBDIVISION.**—In this way small paddocks can be held for the young sheep. The flock, however, should not be left on them for more than three to four weeks at a time.

(3) **BURNING OFF PADDOCKS.**—The burning off of paddocks wherever possible in spring and summer destroys many young worms.

(4) **THE USE OF LICKS.**—As the natural pasture of most of the worm areas is deficient in mineral matter (phosphorus and calcium) the provision of the following lick during the dry period of the year is recommended:—

	Parts.
Dicalcie phosphate (35 to 37 per cent., P_2O_5) ..	40
Salt	60

Note.—Those areas of South Australia in which parasitic gastro-enteritis of sheep is common are Kangaroo Island, the coastal areas of Eyre's and Yorke Peninsulas (*Trichostrongylosis* is particularly bad in these coastal parts), the South-East, the area south of Adelaide, the Lakes district of the Murray Mouth. It has also been observed in the Auburn, Clare, and Angaston districts and also the Hills district.

INFECTIOUS ENTERO-TOXAEMIA OF SHEEP.

Recently this disease was investigated in Western Australia by Bennetts, and later in Tasmania by Oxer, and the results of their investigations have been published in the Council for Scientific and Industrial Research's Bulletin No. 57 and Pamphlet No. 35.

There is little doubt that the Western Australian disease is identical with that disease of sheep in South Australia known as "Braxy-like Disease" and "Stink-wort Poisoning," and also with that disease in lambs called "Pulpy Kidney."

As this disease is a common one and is the cause of serious losses amongst sheep and lambs in this State, a summary of the results of this work should be of interest.

Infectious entero-toxaemia can be described as a rapid poisoning by a powerful toxin (poison) manufactured under certain conditions in the small bowel of the sheep by a special germ, the *Bacillus ovitoxicus*, during its growth there.

DISTRIBUTION.—The disease is widespread in the agricultural areas of South Australia. It appears to be confined to the cultivated areas and districts where top dressing of pastures has been carried out. It is common in the old settled wheat areas of the Mid-North.

INCIDENCE.—The disease is peculiar in that the mortalities from it vary considerably from year to year; it will appear in one district for one, two, or three years, and then apparently die out; again, it may appear on a certain farm whilst adjoining properties will be free from it. The following facts in regard to its liability to occur are known:—

- (1) **Seasonal Occurrence.**—The disease occurs during autumn, winter, and early spring. Losses generally follow after the first rains of the season (March-April), and at this time the disease usually makes its

appearance in the wheat areas, where the history is invariably that the sheep at the time of the occurrence of losses were grazing mainly on Stinkwort (*Inula graveolens*). In other districts outbreaks coincide with the appearance of greenfeed. The disease continues throughout the winter months and up to late October. The greatest losses usually occur at the beginning of the season and towards the latter part (spring) when lambs particularly are affected. Good seasons with a "flush" of feed are considered to be the worst. A point of importance is that outbreaks of the same disease have been observed in sheep running on dry pea stubble in the summer months, especially after a thunderstorm, presumably as a result of their gorging on swollen peas.

- (2) *Yearly Variation*.—Mortalities are greatest on farms or in districts where the disease occurs for the first time. On the other hand in those areas where the disease is well known the death rate is low except in flocks newly introduced from clean areas.
- (3) *Species of Animals Affected*.—It is naturally confined to sheep.
- (4) *Breed and Sex*.—They have no particular significance except that farmers consider that crossbred lambs, which fatten and mature more rapidly, are more frequently affected than Merino lambs.
- (5) *Age*.—Sheep of any age from three weeks old onwards may be affected; young sheep are probably more frequently affected.
- (6) *Condition*.—Sheep in good condition, particularly rapidly fattening animals, are chiefly affected. Sheep in store condition are occasionally affected.

SYMPTOMS.

In an outbreak the losses are usually spread over a considerable period (two months or more), and are never great at one time. The owner usually finds the affected sheep dead in the morning near the camp. The period of sickness is short (two to four hours), and only occasionally does the farmer notice signs of it. Sheep frequently show symptoms after being driven; they lag behind the flock, and are frequently left when camp is broken. There is a staggering gait with "knuckling over" of fore limbs. The animal soon goes down, and either lies quietly until it dies or less commonly exhibits up to the point of death more or less violent galloping movements. This convulsive type is more frequently seen in lambs than adult sheep. Salivation and champing of the jaws are common. Bloating may become marked before death.

POST-MORTEM FINDINGS.

On examining the carcass the owner finds that it is invariably that of a well-nourished animal. It is blown up, and the skin which is not covered with wool is often dark blue in color (fermentative changes). Signs of recent scouring are usually present. On opening up the carcass the rumen and small bowels are noticed to be full of gas, and contain less solids than normal. There is a variable amount of fluid in the belly and lung cavities and in the heart sac. On opening up the small bowel the lining appears redder than usual. The kidneys are extremely soft and "pulpy."

PREDISPOSING FACTORS.

The germ (*Bacillus ovispastus*) has been found in the soil of affected properties. It thrives in cultivated and improved soils. Improvement of pasture usually means increased carrying capacity, and this is productive of heavier soil contamination. Healthy sheep can take the germ into their digestive canal along

with food and water, and under normal conditions they are not affected. However, there are certain factors which cause it to grow rapidly there, and in the process give off the toxin which is absorbed into the body of the sheep and so poisons it. These factors are:—

- (a) *Sluggishness of the Small Bowel.*—When fat sheep in good condition are feeding on an abundance of feed low in fibre content and taking practically no exercise, the small bowel becomes lazy in its action. In support of this there is the evidence of sheep owners who have had beneficial effects from compulsory daily exercise and the feeding of dry feed rich in fibre. Again, it is well known that turning the flock out on “scrub” country will prevent and even stop the disease. The beneficial effect is probably due to the high fibre content of the plants growing on this type of country. Again, there is evidence that the wet pasture in the early morning is “dangerous,” and that where sheep are shut up at night and turned out to pasture late in the morning the disease does not occur. The wet feed may cause bowel sluggishness.
- (b) *Bowel Injuries.*—When sheep are grazing on stinkwort it is known that the barbed hairs of the pappus attached to the fruits of the plant enter the lining wall of the small bowel. The injury caused evidently provides conditions favorable for the growth of the germs.
- (c) *Soil Factors.*—Cultivation, increased stocking, and the presence of decaying sheep carcasses on a property all make for a heavy contamination of the soil with the bacillus. It has been observed on some properties that sheep feeding close to the ground and for some time taking in with the feed, soil presumably containing large numbers of the germs, can develop the disease. Under these conditions sheep in store condition may become affected.

RESISTANCE TO THE DISEASE.

On those farms where the disease has occurred for a number of years, it is found that the death rate in flocks which are bred on these properties shows a steady decline, and losses may cease entirely. It would appear that such sheep develop a tolerance to the disease. The heaviest losses are usually experienced in flocks brought into affected districts from localities where the disease is unknown.

TREATMENT.—Owing to the nature of this disease, *i.e.*, a short illness followed by sudden death, treatment is not practicable.

METHODS OF CONTROL.

(1) **PREVENTIVE INOCULATION WITH VACCINE.**—The production of a tolerance to the disease by means of vaccination is proving successful. The vaccine has not yet been made available for general issue. It should be used only under the directions of a qualified veterinary surgeon. The Stock and Brands Department will be pleased to discuss any outbreaks of this disease with sheep owners, and advise on whether vaccination would be a practicable measure. The vaccine would cost about 1½d. for the treatment of one sheep.

(2) **FEEDING OF FIBRE.**—Feeding with chaff is recommended. With abundance of greenfeed available, it might be necessary to yard sheep in order to induce them to eat the dry feed, but in flocks where heavy losses are experienced this would be worthy of a trial. The value of “scrub country” where this can be obtained has already been indicated.

(3) **EXERCISE.**—Compulsory exercise should be beneficial, and some sheep farmers claim to be able to prevent the disease by "dogging" the sheep around the paddock each morning. Enforced exercise should begin before the disease appears, or right at the commencement of an outbreak. Where conditions are suitable, travelling the flock may be very helpful.

(4) **THE AVOIDANCE OF CLOSE GRAZING.**—This is advisable as far as possible on farms where the disease is prevalent.

(5) **DISPOSAL OF CARCASSES.**—The germ increases in carcasses of sheep which have died from this disease, and heavy contamination of the soil results from this source. All such carcasses should, therefore, be destroyed as soon as possible. This also applies to the bodies of all other animals (including rabbits) which die on the area. It is quite probable that they may be carriers of the germ. Carcasses are best destroyed by fire. If this is impracticable they should be buried deeply in an area set apart for the purpose. (*Note.*—The proper disposal of carcasses is a part of good farm management, and should be carried out on all farms.)

(6) As it is very probable that sheep continually exposed to the disease can acquire a tolerance to it, sheep owners in affected districts should avoid as far as possible the introduction of sheep from districts where the disease does not occur. It should be the aim to breed from the flock already on the property. The vaccination of new purchases (rams, &c.) could be tried after their introduction to affected properties.

SOME NOTES ON "INFECTIOUS ENTERO-TOXAEMIA" (PULPY KIDNEY) OF SUCKING LAMBS.

1. The disease affects unweaned lambs which are in high condition and running on rich pasture. The greatest losses are found to occur on pastures having a large proportion of clovers in their composition. Under these conditions the ewes are giving a copious supply of milk, in addition to which the lambs are eating a high protein grass diet, and it is evident that these conditions help to bring about the disease. It is while the pastures are still young and succulent that the greatest mortality occurs.

2. The disease has been observed in lambs three to 13 weeks old.

3. Ewe lambs are mostly affected. It is considered that the castrating and tailing of the male lambs causes a greater check than the tailing of the ewe lambs, and that this explains the greater occurrence of the disease in the latter after marking.

4. Twin lambs appear to be very rarely affected.

5. The greatest mortality occurs in the mutton types.

6. **MEASURES FOR CONTROL.**—Very little can be suggested beyond what has already been advised, but the following can also be tried:—

(a) Yarding of the ewes and lambs for 24 hours once a week has given very good results, and it has this advantage that it does not cause any noticeable check. The principal difficulty is that on most farms the ewes are not drafted into mobs as they lamb. It is but rarely that the size of the paddocks precludes this. The preventive measure here advocated can only be properly applied where this system of drafting has been carried out.

(b) *Tailing and Marking.*—These cause a check in the lambs. Further work on this disease should, however, result in more effective means of preventing its occurrence in sucking lambs.

THE FLAX INDUSTRY.

The Director of Development recently published a report of the investigations of his department on the possibilities of developing the flax industry in Australia. The investigations were conducted by the Director (Hon. J. Gunn) in co-operation with Mr. E. W. Robinson (Agricultural Adviser) and Mr. C. V. Lohan (Investigating Officer) at the instigation of the Federal Minister in control of development, who asked that particular regard should be given to the following points:—

The present position of the industry; the possibilities of stimulating production; the effects of the Flax and Linseed Bounties Act of 1930 upon the industry; the extent of the home market for flax and linseed, and the possibilities of developing an export trade; the economics of the industry in relation to other agricultural industries; the suitability of climatic and soil requirements for flax and linseed production; the possibilities of stimulating production by means of organised educational propaganda carried on in conjunction with the respective States; costs of production, market prices, including world prices and marketing arrangements.

The report deals in detail with various points raised in the above terms of reference, and ends with the appended summary and conclusions arrived at from the investigation.

SUMMARY.

Russia produces considerably more than half of the world's requirements of flax fibre, and in combination with the Baltic countries of Latvia, Lithuania, Estonia, and Poland supplies more than 80 per cent. of the demand. The supply of the world's fibre has always come from countries where wages are low. In the last three years, although there has been a severe shrinkage in world production, Russia continued to increase its area under cultivation, and in 1930-31, with a record of 536,800 tons of fibre, greatly exceeded its pre-war output. Figures for 1931-32 are not available, but a still further increase in production is predicted.

Attempts made to stimulate and expand the industry in Great Britain, Northern Ireland, Canada, and the Kenya Colony since the war have been successful. In Belgium, where the world's best fibre is produced, cultivation has steadily declined during recent years, and in France, Holland, and Germany, as well as in the Baltic countries, the area under cultivation has decreased.

For many years cotton has been usurping the place of flax fibre in the manufacture of such widely used articles as canvas and duck, and owing to the severity of this competition Belfast and Scottish mills are concentrating more and more on the manufacture of fine linens. A feature of the enormous decline of British imports of fibre for manufacturing purposes is that, whereas low-grade eastern European supplies have decreased by more than 73 per cent. since pre-war years, Great Britain's trade with other countries, notably Belgium and Holland—the home of the best fibres, shows a decrease of only 22 per cent.

For upwards of 30 years flax has been grown in small quantities in parts of Gippsland, Victoria, but there has been no sustained production in any other portion of the Commonwealth. For 18 out of the past 26 years production has been assisted either by bounties or guarantees of a fixed price, but despite this encouragement the industry has failed to expand or even strengthen its position. Production was stimulated during the period 1918-21 by guaranteed prices and bonuses which enabled growers to obtain from £5 to £9 per ton for their flax. When the special circumstances which gave rise to the phenomenally high prices of fibre had disappeared there was an immediate contraction in the acreage sown. Except for the special circumstances during the war, Australia has never been able to produce

fibre at a cost which would make export profitable. Even now, after all these years, there is nothing to justify the hope that Australia will be able to grow fibre on a competitive basis with other countries, particularly Russia.

The immediate effect of the Linseed and Flax Bounties Act of 1930 was to increase the area sown to flax in Victoria from 703 acres in 1929-30 to 1,216 acres in 1930-31. Tasmanian farmers also planted some hundreds of acres, but the anticipated large sowing did not take place owing to the complete failure of the Tasmanian Flax and Canvas Co., Ltd. This company was formed in 1927, and was an applicant before the Tariff Board for a bounty on fibre and linseed. Farmers in both States were either guaranteed or led to believe they would be paid from £5 to £6 per ton for all the straw they produced. These undertakings were not fulfilled, and many farmers received no payment at all but, in addition, lost the capital which they were induced to invest in some of the newly-formed companies. Flax is no longer grown in Tasmania, and in Victoria the area has receded to about 800 acres.

The promise of the successful development of the industry in Victoria as implied by the increased acreage in 1930-31 has not been fulfilled. The bonus payable on both fibre and linseed is paid direct to the millers, and, in the case of the Drouin district, there can be no doubt that, were it not for this assistance, the growers would have been compelled to accept less for their crops. Nevertheless, up to the present the crop has not been grown in quantities sufficient to keep the Drouin mill working to its full capacity.

In the section dealing with milling costs, the operations, in detail, of the Drouin mill have been analysed. Present-day world conditions have created an artificially high price for fibre in Australia, and so long as these continue it appears probable that locally produced flax will command a high price. The company contends that, on the basis of an intake of 1,500 tons of crop a year it could show a return on capital and, without the aid of the bounty, continue to pay growers £3 14s. 11d. per ton. It cannot be too strongly emphasised, however, that this would depend upon the company's products commanding the prices expected this year, viz., fibre £65 per ton, tow £7, linseed £18.23, and chaff £2, but it is impossible to express any opinion on this point other than to stress the fact that these prices are largely dependent on the continuance of the present rate of exchange, and the continuance of the high price of linseed.

Even if the claims of the Drouin Company, as set out in the preceding paragraph were realised, they would still fail to provide satisfactory evidence that the industry could be expanded to any considerable extent. The uncertain and restricted nature of the local market for fibre, and the danger of over-production, are matters for serious consideration. Furthermore, if linseed were produced on a large scale, the bulk of it would have to be sold to the oil manufacturers in competition with the Indian and Argentine seed, which is imported free of duty. Linseed imported for purposes other than the manufacture of oil, the feeding of stock, or for sowing is dutiable at the rate of 2s. British preferential and 2s. 6d. general per cental, hence the strictly limited market for the local product at £18 per ton. Last year was the only year in which the company made a profit, and this was possible only because of the bounty. This year a further improvement is anticipated, but only because the high prices realised for linseed, plus the bounty, are sufficient to more than offset the loss incurred on fibre production, even at £65 per ton.

All the evidence tends to show that on the average the general quality of Australian fibre can only be ranked as from medium to poor. Doubtless good samples are obtained, but the general suitability of the fibre for textile purposes, apart from twines and cordage, cannot be determined except by large-scale commercial tests. Up to the present this proof is lacking. Unfortunately the investigation officers were handicapped by their inability to discover persons who had been

trained in the various technological branches of flax fibre, and who might discuss the problems of the Australian industry from a sound practical knowledge of cultural requirements processing methods, and textile suitability. If, as appearances indicate, the relatively poor quality of Australian fibre results from one or a combination of all the following factors, then the prospects of the ultimate success of the fibre industry are most discouraging:—

- (1) Unsuitability of climatic conditions during the growing period.
- (2) Growing a crop both for linseed and fibre.
- (3) Cutting the crop with a reaper and binder instead of pulling it by hand or machine.
- (4) Unsuitability of the climate owing to its variability for the dew retting of the straw.

It seems highly probable that the practice of dew retting may be a potent cause not only of the variability of quality of Australian fibre, which was so strongly emphasised by the twine and cordage manufacturers, but also of the low ratio of fibre to tow. Obviously there can be no control of the climatic conditions during the process of retting, and the possibility of under-retting or over-retting is apparent. There is an absence of data upon which to judge between the climatic conditions of Russia and the Baltic countries, where dew retting is partially practised, and certain parts of Australia. Furthermore, dew-retted fibre in Europe does not rank amongst the highest-grade qualities. If a textile industry were to be contemplated, the first step to be taken should be the testing in bulk of the Australian fibre to ascertain whether the fibre possesses the necessary spinning qualities for the particular textiles proposed to be manufactured.

DISTRIBUTED FROM

95-97, NORTH TERRACE, ADELAIDE.

(H. V. MCKAY MASSEY HARRIS PTY. LTD).

It would appear that Australian straw, while returning a higher percentage of seed per ton than European straw, yields a much lower percentage of fibre per ton. According to Professor F. Bradbury, Municipal Institute, Belfast, 100 tons of crop should yield about 31 tons seed and chaff, leaving 69 tons of straw for retting having a retted weight of 55.2 tons from which 9 tons of fibre and 3 tons of tow should be obtained. The average recovery of fibre at the Drouin factory during the seasons 1929-33 per 100 tons of crop was fibre 5.93 tons and tow 8.47 tons.

There is insufficient evidence that the decorticating machine invented by Mr. N. C. Grigg will obviate the necessity of retting the straw, and that its general adoption will place the industry on a sound footing. The only satisfactory test that can be applied to an invention of this kind is the commercial test, and it must be left to the manufacturers who use the fibre processed in this fashion to determine its suitability and value for their particular purposes. There is this to be said also, that any machine which would abolish retting would not confer its advantages on one country only, but would be quickly adopted by all countries where fibre is produced. Experiments are being made in other countries with machines designed for a similar purpose, and some of these are now being tested commercially.

The examination of growing costs indicates that the growing of flax for linseed might prove a profitable industry during this period of depressed prices, for farmers in certain areas of Gippsland whose usual operations include the growing of cash crops. It is difficult, if not impossible, to arrive at the exact costs of the production of any crop, as this is dependent upon so many variable factors. The main items of expenditure on cultivation and the operations, and on rent would amount to about £4 12s. per acre. There is, as has been pointed out, a limited market for linseed at £18 per ton, and an unprotected and capacious market at £14 per ton. The average yield in the Drouin district amounts to 12 bush. per acre.

CONCLUSIONS.

From the facts and from the evidence obtained in the course of the investigation, the following conclusions are arrived at:—

(1) Flax has been grown in small quantities in selected areas in Australia for upwards of 30 years, but it was impossible during that period to establish a profitable export industry for the sale of fibre. The world's price of flax expressed in gold currency is at present close to the pre-war level, and little improvement, if any, can be expected pending a solution of the present crisis. The development of a profitable export trade in fibre, therefore would appear to be out of the question unless more economical methods can be devised for handling the crop and increasing the recovery of fibre per ton of retted straw treated.

Efforts that have been made in this direction are not encouraging. Revolutionary methods of treating the straw which would substantially decrease the cost of the fibre have been suggested, but until manufacturers endorse the claim made in respect of the machines which have been invented by their willingness to utilise this particular fibre, it would be idle to pass any comment.

(2) Linen goods are not manufactured in Australia, and the only local market available is that provided by the soft fibre requirements of the rope and cordage manufacturers, the limitations of which can best be appreciated from the fact that imports of Italian hemp have averaged only 383 tons for the last three years. On the basis of the results obtained in Gippsland during the past four years, the production of 383 tons of flax fibre would necessitate the cultivation of approxi-

mately 4,000 acres of crop, but even this restricted area would probably exceed the present limit of economic expansion, for it must be remembered that Italian hemp, even if largely displaced by Australian flax, would still be a necessary requirement of the rope and cordage manufacturers. There does not appear to be any likelihood of a linen industry being undertaken in Australia but, even if it were, there would be no guarantee that Australian flax fibre would measure up to the quality demanded by the trade.

(3) Whilst the flax fibre continues to command its present price in competition with Italian hemp there may be possibly some expansion of the present acreage. In the whole of the circumstances, however, with the prospective development of an Australian flax industry definitely restricted to the narrow dimensions already indicated, and aggressive policy of expansion should be avoided.

(4) Experience has shown that climatic conditions render a great part of Australia's farming territory unsuitable for the production of linseed. Heaviest yields are obtained from certain districts in the south of Victoria and from Tasmania. Nowhere in Australia, however, is flax grown solely for seed. As flax growing is opposed to the declared policy of the Tasmanian Department of Agriculture for the economic development of the farming industries of that State, little if any, production may be expected in Tasmania.

The replies of the Agricultural Departments of the other States show that unsatisfactory results have attended the efforts to grow linseed, and until it can be demonstrated that the crop is profitable it would be useless to endeavor to interest farmers in its cultivation. Estimates of the cost of the production indicate that a yield of 12bush. of linseed per acre at a price of £14 or £15 per ton would, at the present time, just about provide wages and pay expenses. From the data available in Victoria it appears that this yield, although it has been obtained from a restricted acreage, is considerably higher than the average annual production per acre in those districts which have been tested for flax growing. In the circumstances it would be a highly questionable policy to encourage radical departures from existing farm practices, particularly where they would involve the breaking up of valuable pastures in order to devote them to the growing of linseed. Moreover, should it be actually shown that the growing of linseed is, under the conditions of the moment, more profitable than the growing of cash crops such as oats, potatoes, or hay, this fact would furnish no ground for the belief that its cultivation would become a permanent feature of farm management. The history of the industry proves that other crops are favored under normal conditions. There is no evidence, therefore, to justify the hope that the growing of linseed will become an important and stable industry in Victoria.

(5) It has been submitted that consideration should be given to the stimulation of production by means of organised propaganda carried on in conjunction with the respective States. Obviously, in view of the conclusions already expressed, propaganda is not to be commended. Even were the prospects of the industry brighter than they appear to be to-day the success of any attempt to stimulate production on a large scale would depend upon the farmers' co-operation. Many growers in Victoria and Tasmania are still smarting under the unhappy memory of their recent experiences, and until this is effaced the task of the educationist will be a difficult one.

(6) In view of conclusions in paragraph 1, 2, 3, and 4, no suggestion can be made whereby the money set aside under the provisions of the Flax and Linseed Bounties Act of 1930 can be successfully utilised for the further development of the industry.

THE DRAUGHT STALLIONS ACTS, 1932-1933.

The July number of this *Journal* (page 1371) contains a summary of the Draught Stallions Act, 1932. This Act was amended in Parliament during the present session by the Draught Stallions Act Amendment Act, 1933, which is now in force, and which makes the following amendments:—

1. Draught stallions which were three years old and over and which were within the State on July 1st, 1933, are permitted to travel notwithstanding that they do not possess a Government certificate of soundness. This exemption does not, therefore, apply to draught stallions which were two years old on July 1st, 1933, or to draught stallions which were introduced into the State subsequent to July 1st, 1933. The exemption referred to remains in force only until June 30th, 1938.

2. With regard to age, a draught stallion born in any calendar year will be deemed to be one year of age on July 1st of the next calendar year, and thereafter the age of the stallion will be computed from July 1st.

3. After the 1st day of July, 1934, no Government certificate will be issued unless the draught stallion conforms to a reasonable standard in respect of type, breeding, and conformation. No draught stallion for which a certificate of soundness has been issued during the present season will be refused a certificate at any subsequent examination except on the grounds of unsoundness.

4. Appeals against the decision of the examining officer for the refusal of a certificate for a draught stallion which is below a reasonable standard in respect of type, breeding, and conformation may be made in the same manner as appeals against unsoundness except that in this case the Appeal Board is constituted by the Chief Veterinary Officer and two members who are competent judges of draught stock.

5. After July 1st, 1938, the owner of a four or five year old draught stallion which is refused a certificate on the grounds of unsoundness, and where the stallion had been issued with a certificate the preceding year, may apply to the Minister for compensation.

6. The amount of compensation is based upon the market value of the draught stallion on the 30th June preceding the examination when the stallion was refused a certificate and is assessed by a Valuation Board consisting of the Chief Veterinary Officer and two members who are appointed from a panel of competent judges of draught stock, one of the members being nominated by the owner of the stallion. The amount of compensation in the case of a draught stallion which is four years old is one-half the market value and in the case of a five-year-old stallion is two-thirds the market value on June 30th preceding the examination. The decision of the Valuation Board as to the market value is final.

7. The Minister may, upon proof of the castration of a draught stallion, pay the whole or any part of the amount of the compensation assessed by the Valuation Board, and the decision of the Minister in this regard is final.

8. On and after the 1st July, 1938, the exemption provided in the case of draught stallions which were within the State on July 1st, 1933, and the exemption of draught stallions which are used only for the service of mares which are the sole and exclusive property of the owner of the stallion terminate. The Act then comes fully into force, and all draught stallions two years old and over must possess a Government certificate of soundness and approval.

NOTE.—The provisions of the Principal Act as summarised in a previous issue of this *Journal* remain in force with the exception of the above amendments, and should be read in conjunction with them.

THE "LUCERNE FLEA" PROBLEM IN SOUTH AUSTRALIA.

[By J. DAVIDSON, D.Sc., The Waite Agricultural Research Institute,
University of Adelaide.]

(Paper read at 44th Congress of the Agricultural Bureau, September, 1933.)

INTRODUCTION.

The lucerne flea is the most serious pest of clover and lucerne pastures with which the South Australian farmer has to contend; in favorable, wet seasons it may be also troublesome on other crops.

The pest is a small, primitive insect belonging to a group of insects known as "springtails," which chiefly inhabit the soil surface. This particular species, *Sminthurus viridis*, is widely distributed in Europe; in Australia it occurs in various parts of the southern States. It is able to increase in numbers to a remarkable degree when food-plants and weather conditions are favorable.

Mr. W. L. Summers (*Journal of Agric. and Indus.*, S.A., 1900, p. 18) refers to the insect as occurring in numbers in lucerne around Morphettville about 1884. The species is now an economic pest throughout the better rainfall districts of the State. Experimental work on the biology of the insect, carried out at the Waite Institute, has shown that the climate of South Australia, as is also the case with Western Australia, favors the occurrence of the species in large numbers during certain months of the year.

In 1927, Mr. F. G. Holdaway (Pamphlet No. 4, Coun. Sci. and Ind. Res.) published a concise account of his investigations on the lucerne flea, which were carried out at the Waite Institute. The writer has made a detailed study of the problem during the past two years, and the results of these investigations will be published in detail as a bulletin. In addition, the Division of Economic Entomology of the C.S.I. Research has been investigating the problem in Western Australia. Officers of the Departments of Agriculture in the States where the pest occurs have been also investigating certain aspects of the problem.

In Europe, certain investigators, notably W. M. Davies and D. S. MacLagan, have added considerably to our knowledge of the habits of the insect. In 1928, Professor E. Malenotti referred to this species as damaging young, growing wheat near Pisa in Italy (*Atti dell'Accad. d'agricoltura, sc. e lettere di Verona*, vol. 5, p. 5).

1. LIFE HISTORY AND HABITS OF THE INSECT.

The adult insect is about $\frac{1}{12}$ in. long; it inhabits the soil surface and feeds particularly on clovers and lucerne, also on certain broad-leaved weeds like "Cape weed." It will, however, feed on a wide range of plants, and when in large numbers grasses and young cereal crops may be seriously damaged. The insects eat out the green, central portion of the leaves (mesophyll); and damaged leaves have a characteristic, silvery appearance.

The females lay their eggs in batches on the soil; a batch generally consists of about 60 eggs, but the number may be much greater or less than this; a female will lay about 100 or more eggs during her life, in two or more batches, with an interval of about 10 days between the laying of each batch. Each egg, as it is laid, is covered with a brown fluid excreted by the female. For this purpose the female takes in by the mouth, free moisture and soil during the oviposition period. The excreted fluid, therefore, consists of ingested soil particles and secretions produced by the insect; it dries on exposure to the air, forming a covering over the eggs, which is the same color as the soil. This covering safeguards the eggs against egg-eating mites, &c., prevents their rapid dessication, and provides them with adequate moisture; it also serves to hold the eggs in a batch together.

When moisture is favorable, the eggs develop. At a temperature of 52° F. their development takes about 28 days; at 60° F. about 15 days. When the conditions at the soil surface are dry, development of the eggs is retarded, and may be completely arrested. Certain partially developed eggs can withstand dryness for long periods and remain viable. It is these eggs which carry the species over the dry summer months; they hatch with the autumn rains.

The newly-hatched nymphs are active, and eat small holes in the leaves of the food-plant, giving it a speckled appearance. With a mean monthly temperature about 50° F. the insects become adult in about 50 days, and at 60° F. in about 30 days.

The insects are susceptible to dryness. In warm, dry weather they die off rapidly in exposed situations, but may persist in local, moist places. During the summer months, therefore, the insect is generally absent in pastures.

Cold, wet conditions at the soil surface also increase the death rate, so that the number of insects is less in the mid-winter months, especially in the more elevated colder districts of the State.

Fig. 1. Illustrating the density of the population of *S. viridis* in lucerne at the Waite Institute during 1932; the mean air temperature and total rainfall, each week, is also shown. The points on the population curve represents the numbers of the insects present each week, in a sample area of 7-10ths of a square foot.

2. WHY DO THE INSECTS INCREASE IN SUCH LARGE NUMBERS?

The economic importance of the lucerne flea in South Australia is due to the large numbers of the insects which develop during the favorable months of the year. When rainfall is adequate, mean monthly temperatures between about 52° F. and 60° F. favor increase in the population if food-plants are available. These conditions occur normally from April or May to September or October, although in some districts the insects are less active during the mid-winter period. In wet years the period is longer, in dry years shorter. It is also longer in the more elevated districts, and also in the south-eastern districts, owing to the moisture in the pastures persisting for a longer period.

A population curve is given in Fig. 1 which shows the numbers of *S. viridis* in lucerne at the Waite Institute during 1932. Three samples were taken twice each week, the area covered by the three samples on each occasion being $\frac{7}{10}$ ths. of a square foot. If we consider the insects to have been evenly distributed throughout the lucerne, the number of the insects per acre reached the high figure of 130 millions per acre in May, and dropped to 13 millions per acre during the mid-winter months. Actually, however, the high density of the population is only temporary, and does not occur throughout the area at the same time, as the insects move outwards from heavily-infested portions owing to competition for space and food.

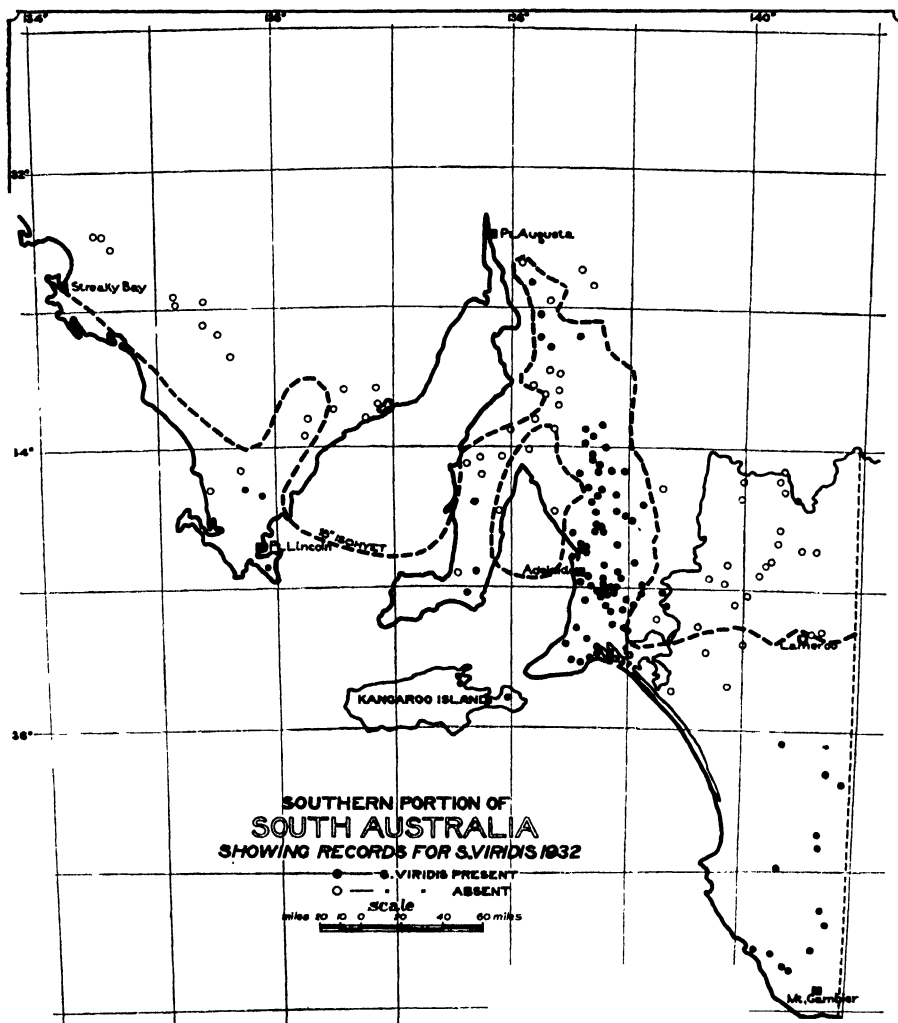

Fig. 2. Illustrating the distribution of *S. viridis* in South Australia from records taken during 1932.

It is clear from Fig. 1 that the insect disappears in the dry season, and that the over-summering eggs hatch in the autumn. There are two periods of greatest increase in the population of the insects, namely, autumn and spring. This is due to the favorable moisture and temperature during these periods. It is owing

to the steady moisture conditions and favorable temperatures during the wet season, together with the ability of the eggs to withstand the dry season, that *S. viridis* is such a serious pest in this State. Rainfall is the dominating factor; and in dry years the area of severe infestation will be much less than in wet years.

3. POSSIBLE DISTRIBUTION OF THE SPECIES IN SOUTH AUSTRALIA.

The density of the population of the insects in any district will depend upon (1) the number of generations of the insect which develop, (2) the number of successive months in which moisture and temperature are favorable, and (3) the availability of suitable food-plants.

In the Northern districts of the State, also in portions of the West Coast and in the upper South-East, the normal rainfall is not adequate to enable the species to increase in numbers. It may occur in local moist situations or on irrigated soils. Furthermore, the light, sandy soil and vegetation is not favorable for the insect.

In 1932, through the courtesy of the General Secretary of the Agricultural Bureau (Mr. H. C. Pritchard), a letter was sent to all Branches of the Bureau requesting information regarding the occurrence of the lucerne flea, and 170 definite records were obtained. These localities have been marked on the map shown in Fig 2.*

It is seen that the 15in. annual isohyet gives a fair boundary to the possible distribution of the species in South Australia. It can occur in local moist situations and on irrigated soils outside this area, but the more serious infestations will occur in the better rainfall districts within this boundary.

In the elevated eastern portion of the Upper and Lower North it will seldom occur in serious numbers owing to the cold, wet conditions during the winter months.

In the West Coast districts, the upper South-East, and Yorke Peninsula the sandy character and alkaline reaction of the soil is not favorable for the insect. The conditions are favorable in the area around Port Lincoln and Maitland, and also on the reclaimed swamps in the Murray Bridge district, owing to the character of the soil and irrigation.

In dry years the area of severe infestation will be confined to the wetter districts. When a sequence of wet years occurs, the area of infestation will be greater, corresponding somewhat to the situation as shown for the year 1932.

The species has reached its permanent limits of economic distribution. The intensity of its increase in numbers will vary from year to year in any district; it will also vary in one district compared with another. Where soil and rainfall are favorable, increase in the density of the population may be expected in favorable years in suitable pastures such as clover or lucerne.

4. HOW HAS THE SPECIES BECOME SO WIDELY DISTRIBUTED THROUGHOUT THE STATE?

We have seen that about 1884 the occurrence of the species as an economic pest appears to have been confined to a very restricted area. Owing to the wide range of food-plants on which the insects feed, its spread throughout the area climatically suitable for it would naturally be expected. This would be assisted by the spread of favorable weeds, such as Cape weed. Improvement in pasture areas in the agricultural districts, particularly the increased planting of lucerne and clovers, has undoubtedly favored the spread of the insect. In the returns

*I would like to express my thanks for the helpful co-operation of members of the Agricultural Bureau in this respect.

for 1921-22 the area under sown grasses, hay, clover, &c., was practically nil; in the returns for 1931-32 the total area was 131,710 acres. The areas under lucerne for these periods were 28,000 and 62,709 acres.*

Owing to the character of the egg batches and the resistance of the eggs to dryness, the distribution of the species from one district to another could be readily brought about by produce or containers contaminated with soil or surface debris. It is evident, for example, that Subterranean Clover seed from an infested district, if contaminated with surface soil, could be a source of infestation in another district. It is the appreciation of this fact which underlies the restrictions regarding the entry into non-infested areas of particular produce from areas infested with lucerne flea.

The insects could be carried in green fodder and readily distributed locally. The eggs, surrounded with soil, could adhere to the feet of stock or implements and be readily carried to other districts.

Fig. 3. Illustrating the effect of spraying lucerne with lime-sulphur; the portion of the plots in the foreground was sprayed on May 9th, 1933; the portion in the background was unsprayed; photograph taken June 19th, 1933.

5. RECOMMENDATIONS FOR DEALING WITH THE PROBLEM.

From what has been said about the biology of the insect it is evident that the problem offers considerable difficulty, owing to the widespread distribution of the insect throughout the better rainfall districts of the State. With any method of treatment of infested pasture the farmer is always faced with the re-invasion of the pasture from the surrounding areas.

In restricted areas palliative measures, such as spraying, will be temporarily effective. In the case of lucerne it has been shown that, by spraying with lime-sulphur, practically complete control can be obtained (Davidson, J., *Journ. Dept. Agric.*, South Australia, vol. 36, 1933, pp. 994-1006). The spraying must be thorough and carried out at the correct time in relation to the habits of the insect.

*I am indebted to the Assistant Government Statist of South Australia for these figures.

It is considered that one application in the autumn, followed by a further application if necessary in the spring, will give satisfactory control, provided measures are taken to prevent re-infestation of the crop from the surrounding area. The economics of this method will depend upon the value of the crop and the thoroughness with which the control measures are carried out.

A number of spraying and dusting experiments have been made with various materials, in co-operation with the Department of Agriculture. It is unnecessary to discuss these in detail here, but I would like to express my thanks to the officers of the Department for their helpful co-operation in the work; and in particular Mr. R. C. Scott, who arranged for the experiments to be carried out.*

With larger pasture areas, spraying or temporary mechanical methods of control are impracticable. There is, however, one aspect of the infestation in such areas which deserves attention. It is commonly observed that the lucerne flea appears in numbers earlier in the autumn in low-lying, damp situations, for instance, along a creek. As the numbers increase the insect spreads over a wider area and infests crops growing in these situations. With the onset of the wet season these situations afford centres for more widespread infestation. It would appear to be economical to treat such local areas early in the autumn.

From the detailed knowledge which has been obtained regarding the habits of *S. viridis* and the causes of its occurrence in economic numbers, there appears to me to be two broad lines of research along which future investigations could be profitably developed.

A. Modifications in the Development of Pasture Areas.

The trend of the modern development of pasture work is towards the establishment of suitable grasses mixed with clover. Grasses are lightly attacked by *S. viridis*, and where these are the only available food-plants its increase in numbers will be small. The investigations on pasture improvement at the Waite Institute show that clovers are desirable in a grass pasture; they provide the nitrogen necessary for the grasses. In such pastures the clover plants may be considerably affected by the lucerne flea, owing to preferential feeding on these plants. In the warmer months, however, when active growth occurs, the clovers will grow away from the attack; in the meantime the grasses afford adequate grazing. By the establishment of grasses with Subterranean Clover the losses due to the insect will be reduced.

There are certain natural clovers, for instance "Haresfoot" clover, which, although unfavorable fodder plants, give nitrogen to the soil, and are therefore beneficial for the growth of grasses. These clovers are unfavorable for the lucerne flea, which appears to be due to their hairy character and less succulent growth; it may also be due to difference in the quality of the sap.

A useful line of investigation would be a study of the association of clovers and the growth of grasses such as *Phalaris* and Rye grass in relation to infestation of the pasture by *S. viridis*.

Where it is possible, an autumn and early winter fallow would temporarily clear a heavily-infested area. The over-summering eggs would hatch with the autumn rains, and the young insects would die in the absence of food; some of them may, of course, wander into the adjoining area. The extent to which the fallowed area became re-infested would depend upon the measures taken to prevent invasion by the insect from the adjoining area, and also upon the nature of the crop grown.

B. Investigations on the Natural Enemies of the Insect.

It has been shown that the conditions in the pasture, particularly as regards soil type, moisture, and temperature, and the presence of clovers and lucerne, have a marked effect on the fluctuations in the numbers of *S. viridis*. The improved pasture areas in the State have increased considerably during recent years, so

*It may be mentioned that the gardener or nurseryman will find the use of a nicotine spray or dust preferable for tender garden plants.

that the insect fauna in these pastures is not so varied as would be expected in old-established pastures. Further information is required regarding the insect and allied fauna in the pastures of countries where *S. viridis* is present, but does not increase in serious numbers. With this information, together with a knowledge of the effects of local climatic conditions, we would be able to understand more clearly the part played by insect and other predators in restricting increase in the population of *S. viridis*. The Division of Economic Entomology of the C.S.I. Research is investigating this aspect of the problem. In June, 1932, Mr. L. J. Newman (Government Entomologist, Western Australia) and Mr. H. Womersley (then an officer of the Division of Economic Entomology) recorded the occurrence of a species of Snout mite (Fam. *Bdellidae*) as an active predator of the lucerne flea in Western Australia (*Journ. Agric.*, Western Australia, p. 289). In May, 1933 (*Journ. C.S.I. Research*, p. 83), Mr. Womersley (now Entomologist to the South Australian Museum), gave an account of observations and experiments with this species of mite (*Biscirus lapidarius*) in Western Australia, from the time when it was first observed (May, 1931) to the end of 1932.

About 3,000 of these mites were sent from Western Australia in July and August this year by Mr. G. A. Currie, an entomologist of the Council of Scientific and Industrial Research. They have been placed in experimental areas infested with lucerne flea at the Waite Institute and certain other centres. Observations will be made on the ability of the mites to increase in numbers in these varied situations, and the degree to which they are able to restrict increase in the population of *S. viridis*. The Department of Entomology at the Waite Institute and Mr. Womersley are assisting in the development of the work in South Australia.

There are a number of species of mites belonging to the family *Bdellidae* or Snout mites. In general, they are predaceous on soft-bodied insects. An important feature of the observations made on *Biscirus lapidarius* in Western Australia is its occurrence in relatively large numbers in three local situations. In certain instances it appears to have checked increase in the population of *S. viridis*. The mite preys on the lucerne flea, particularly on young individuals. It pierces the insect with its rostrum, and sucks out the body fluids; it also preys on allied species of spring-tails.

6. TREATMENT OF PRODUCE CONTAMINATED WITH THE EGGS OF *S. Viridis*.

It is evident that the chief source of the spread of the lucerne flea from one district to another is the contamination of produce or other materials from infested areas with the eggs of the insect. It is necessary to avoid contamination of these materials with surface soil or leaves, &c., resting on the soil surface.

A number of experiments have been carried out at the Waite Institute in order to find out the effect of certain fumigants, such as Carbon-bisulphide and Hydrocyanic acid gas, on the viability of the eggs of *S. viridis*. The effect of the fumigants varies according to the stage of development attained by the eggs and whether they are in the summer resistant stage or in an active state of development as found during the wet season. Further work is necessary on this aspect of the problem.

BREEDING AND MANAGEMENT OF LIVESTOCK.

The Library of the Department of Agriculture has received from the publishers, Messrs. Whitcombe & Tombs Limited, of Auckland, New Zealand, a copy of a book, "Breeding and Management of Livestock," by A. W. G. Lipscomb. It is an excellent work for schools and colleges where secondary agriculture is taught. The chapters on breeding and feeding dairy cattle are particularly worthy of commendation, and the section devoted to pigs should be extremely useful. At the comparatively low cost of 6s. 6d. the book is one which should be in the hands of every student and persons interested in livestock.

DEPARTMENT OF AGRICULTURE.

Bulls that are purchased under regulations of the Dairy Cattle Improvement Act, and upon which Government pays a subsidy, are available, for two years after purchase, to serve a certain number of outside cows.

The following list, compiled by the Department of Agriculture, shows the names of such bulls and of the people who own them, and indicates also the months until which the respective owners will be prepared to make the services available.

As will be noticed, the distribution of subsidised bulls is now fairly general throughout the State; hence, many of those persons, who in the past have found it difficult to get the use of a good bull, should not have much similar trouble in the future. And here let it be stated that everyone of these subsidised animals is a registered pure-bred and from a dam of proved productivity under Government official test.

The maximum service fee is 10s. per cow.

For the information of cowkeepers, it is pointed out that, although the addresses as given in the following list are those to which application should be made for the services of the bulls, the bulls themselves may, in a few instances, be located elsewhere.

STATE OF SOUTH AUSTRALIA.

VARIETIES OF WHEAT SOWN, SEASON 1932-1933.

[By W. L. JOHNSTON, Government Statist.]

1. The Government Statist reports that 183 (204) varieties of wheat were reported as sown for the Wheat Crop of the season 1932-33. The total acreage sown for Grain, Hay, and Fodder was 4,274,096 (4,327,153), of which the varieties were not specified for 139,560 (159,449) acres.

2. Particulars of the 16 most popular varieties are given at foot hereof. From these it will be seen that Nabawa 22.13 per cent. and Gluyas 11.54 per cent. once again occupy the first and second place, and accounted for one-third of the total area sown. The Supervisor of Experimental Work in the Agricultural Department (Mr. R. C. Scott) states that Nabawa ripens under adverse finishing conditions, resists flag smut, and is also fairly rust-resistant. He also speaks of the variety 'Sword' as being markedly rust-resistant and as the most important new wheat in cultivation. The area sown increased from 2,922 acres in 1931-32 to 23,047 acres in 1932-33.

3. *The three leading varieties favored in each of the Divisions and their percentage to the total were—*

	1933.	1932.
Central—Nabawa 26, Gluyas 8, Waratah 7.		Nabawa 24, Gluyas 9, Ford 7.
Lower North—Nabawa 24, Waratah 7½, Gluyas 7½.		Nabawa 23, Federation 10, Gluyas 9
Upper North—Ranee, 25, Nabawa 21, Federation 18.		Federn 30, Nabawa 18, Currawa 5.
South-East—Gallipoli 50, Ford 8, Bena 8.		Gallipoli 40, Federation 10, Ford 5.
Western—Gluyas 22, Nabawa 19, Late Gluyas 16.		Gluyas 24, L. Gluyas 22, Nabawa 12,
Murray Mallee—Nabawa 24, Gallipoli 17, Gluyas 9.		Nabawa 20, Gallipoli 14, Gluyas 12.

4. *Varieties Increased.*—The following leading varieties show increases:—Nabawa, 945,869 (802,730); Gallipoli, 325,961 (234,891); Ranee, 305,966 (146,613); Waratah, 209,362 (141,939); Felix, 95,528 (89,145); Dan, 44,776 (40,871); and of the lesser: Aussie, 42,388 (24,058); Faun, 19,792 (16,696); Sword, 23,047 (2,922), and others.

5. *Varieties Decreased.*—Gluyas, 493,085 (570,696); Late Gluyas, 261,352 (324,751); Federation, 170,612 (316,266); Currawa, 130,169 (210,133); Ford, 193,035 (203,250); Sultan, 104,452 (128,976); Caliph, 70,817 (105,163); also Daphne, Sepoy, Canberra, Joffre, Bena, German Wonder, Major, and others.

6. *Sixteen leading varieties of Wheat sown, 1932-33 and 1931-32:—*

Kind of Wheat.	Total Area Sown for Grain, Hay, Etc.		Percentage to Total.		Relative Position.	
	1932-33.	1931-32.	1932-33.	1931-32.	1932-33.	1931-32.
Nabawa	945,869	802,730	22.13	18.55	1	1
Gluyas	493,085	570,696	11.54	13.19	2	2

ORCHARD, VINEYARD, AND MISCELLANEOUS CROP STATISTICS, 1932-33.

(Valuations of Products are subject to revision).

I. ORCHARDS.

Estimated Value of Total Products, £697,646 (£642,436).

1. *Acreage*.—29,109 (29,077) acres, increase 32 acres; trees of bearing age 25,780 (25,835) acres. Approximately 520 acres grubbed—mostly in counties Adelaide 300 acres, Hamley 75 acres, Albert 68 acres, and Frome 24 acres; also 60 acres died out. New planting, 610 acres, was an encouraging feature, chiefly in counties Adelaide 420 acres, Light 84 acres, Albert 34 acres, and Hamley 27 acres.

2. *Production*.—Generally speaking the crops were an improvement on the previous year, the most notable being:—(a) Apples 881,139 (876,328) bush., an increase of 4,811, but 471,125 bush. below the record yield of 1,352,264 bush. in 1927-28. (b) Oranges (calendar year 1932) 575,046 (574,700) bush., increase 346 bush., just surpassed the record established the previous year. Lemons 40,102 (40,258) bush. Other Citrus 4,420 (4,205) bush. (c) Pears 219,576 (199,331) bush., increase 20,245 bush., created a record, the previous best being 213,688 bush. in 1927-28. (d) Apricots 331,700 (250,013) bush., increase 81,687 bush.; this yield has been exceeded only once, viz., 347,080 bush. in 1928-29. (e) Other Fruits.—Plums and prunes 182,278 (142,308), peaches 129,908 (101,959).

II. VINEYARDS.

Estimated Value of Total Products, £2,353,049 (£2,296,042).

1. *Acreage*.—52,479 (52,498) acres, decrease 19 acres. Vines of bearing age 51,026 (50,886) acres. About 10 acres grubbed or died out, chiefly in counties Adelaide 250 acres, Light 160 acres, River Murray districts 128 acres; and this was not quite counter-balanced by new plantings—about 590 acres—chiefly in counties Adelaide 220 acres, Light 184 acres, and Hamley 116 acres.

The acreage was described as follows:—For winemaking 33,325 (33,572) acres, drying 18,668 (18,379) acres, and table 486 (547) acres.

2. *Total Grape Yield*.—139,532 (118,749) tons, increase 20,783 tons; average per acre of bearing age 2.73 (2.33) tons. For winemaking 68,500 (59,550) tons, drying 70,075 (58,529) tons, and table 957 (670) tons.

3. *Wine Made*.—12,000,000 (10,664,546) gallons, increase 1,335,454 gallons, but 170,260 gallons below the average of the previous five seasons, 12,170,260 gallons.

III. DRIED FRUITS.

Estimated value (included in Orchard and Vineyard Sections)

£748,767 (£849,441).

1. *Currents*.—127,796 (156,393) cwts., decrease 28,597 cwts.

2. *Raisins*.—Sultanas 200,872 (159,591) cwts., increase 41,281 cwts.; and exceeding the previous record 188,503 cwts. in 1929-30. Other Raisins, 47,805 (25,096) cwts., increase 22,709 cwts.

3. *Other Dried Fruits*.—Apricots 18,185 (12,881) cwts.; plums and prunes 8,540 (4,918) cwts.; peaches, pears, apples, &c., 10,268 (8,048) cwts.

IV. MISCELLANEOUS.

Estimated value of products £380,000 (£387,709).

Market gardens 1,896 (1,726) acres; pumpkins and melons 341 (338) acres, 2,031 (1,941) tons; tomatoes 496 (603) acres, 174,435 (180,492) bush.; potatoes 6,454 (5,996) acres, 24,814 (24,062) tons—heaviest yield since 1913-14; onions 429 (405) acres, 3,392 (2,994) tons; other root crops 565 (602) acres, 3,228 (3,623) tons; nurseries 158 (150) acres.

V. OVERSEA EXPORTS.

The value of the total overseas exports of the products of vineyards and orchards for the year 1932-33 was estimated at £1,446,553 (£1,562,075), decrease £115,522, the principal items being dried fruits £612,560 (£578,371), wine £704,363 (£800,587), apples £95,339 (£162,455). Complete details of interstate exports are not available, but annually about £600,000 of wine and brandy are exported to the other States.

EXPERIMENTAL FEEDING TESTS CONDUCTED AT PARAFIELD POULTRY STATION.

[By C. F. ANDERSON, Poultry Expert.]

A series of feeding tests are being conducted at Parafield Poultry Station with a view to ascertaining if suitable foods which are obtainable on the majority of our farms can be satisfactorily fed to poultry. The tests are each of 50 White Leghorn pullets, and commenced on April 1st, 1933.

The feeding is as follows:—

No. 1 Test.—Morning—Wet mash composed of 1 part crushed barley, 2 parts wholemeal (by weight), $\frac{1}{2}$ lb. meat meal, 40 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird. Night—1oz. wheat per bird.

No. 2 Test.—Dry mash composed of same proportions as No. 1 Test.

Midday—Green feed. Evening—Wheat.

No. 3 Test.—Morning—Wet mash composed of 1 part bran, 2 parts pollard (by weight), $\frac{1}{2}$ lb. meat meal, 40 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird. Night—1oz. wheat per bird.

No. 4 Test.—Morning—Wet mash composed of 1 part bran, 2 parts wholemeal (by weight), $\frac{1}{2}$ lb. meatmeal, 40 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird. Night—1oz. wheat per bird.

No. 5 Test.—Morning, 2oz. wheat per bird.

Evening—2ozs. wheat per bird. Greenfeed in season.

The following are the numbers of eggs laid by each pen from April 1st, 1933, to September 30th, 1933.

Definite conclusions, however, cannot be given at this juncture with regard to the various methods of feeding. It is necessary for the tests to complete the 12 months before any satisfactory opinions can be formed.

No. 1 Test .. .	3,391	No. 4 Test .. .	3,223
No. 2 Test .. .	2,968	No. 5 Test .. .	1,356
No. 3 Test .. .	2,730		

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

FORTY-FOURTH ANNUAL CONGRESS.

The Forty-fourth Annual Congress of the Agricultural Bureau was held in the Way Hall, Adelaide, on Monday, Tuesday, and Wednesday, September 11th, 12th, and 13th, 1933.

DELEGATES.

The following delegates were appointed by their respective Branches, and the figures indicate the number of sessions for which attendance cards were recorded:—J. Y. Hudd (2), J. R. Hewland (3) (Adelaide); A. J. Pengilly (4), T. B. Flint (5) (Alawoona), W. C. Parish (6), J. L. Laslett (5) (Allandale East); W. Patching (4), W. Sibley (3) (Angaston); G. S. Wurst (0), E. H. Wurst (0) (Appila); R. H. Burns (5), H. D. Noble (5) (Artherton); C. J. Pitt (1), H. H. Pitt (1) (Ashbourne); H. Rollbusch (4), E. W. Mattner (4) (Balhannah); H. Schaefer (4), R. S. Goldney (4) (Balaklava); P. Curtin (0), J. Fradd (0) (Beetaloo Valley); H. D. Eckert (0), J. Vivian (0) (Belvidere); E. R. Moss (5), E. J. Johnson (5) (Berri); H. Paech (4) (Blackheath); G. N. Clark (2) (Black Rock); R. Turner (5), A. Mickell (4) (Black Springs); L. Ashenden (2), F. Berrill (2) (Block E); R. H. Eime (2), E. O. Eime (2) (Blyth); A. S. Just (0), M. A. Cockshell (0) (Bowhill); E. Yelland (4), C. Yelland (3) (Boor's Plains); E. H. Huxtable (3), R. G. Bonython (4) (Borrika); G. Tucker (4), J. Boundy (3) (Brentwood); A. T. Fairchild (5), P. A. Kilderry (6) (Boothorowie); H. H. Martin (4), E. W. Pearson (5) (Brinkley); G. E. Ottens (1), H. Snow (6) (Brinkworth); F. W. Rooke (0), A. Treager (0) (Brownlow); S. Norris (5), W. Norris (3) (Balumbah); R. Durdin (3), L. V. Bell (1) (Buchanan); M. J. Cronin (4), C. C. Cooper (0) (Bundaleer Springs); E. H. Ebsary (5) (Bute); N. G. Stewart (6), D. B. Butler (5) (Butler); J. Murphy (0), D. Cash (0) (Calca); W. H. Todd (2) Caliph; C. Dahl (5), P. Meffert (5) (Chandada); A. R. Haseldine (5) (Charra); M. G. Basey (1), C. G. Terrell (1) (Cherry Gardens); A. Cochrane (6), A. Cox (6) (Chilpuddie Rock); J. Spencer (1), T. Brooks (0) (Clarendon); H. Shipard (6), H. H. Gray (4) (Collie); F. E. Ballard (4), J. C. Wilson (5) (Coomandook); W. L. Redman (4), R. Childs (4) (Coonawarra); J. McCallum (3) (Copeville); K. A. Trigg (5), E. A. Pfeiffer (5) (Cummins); A. A. Voumard (5), A. E. Forbes (6) (Cungena); J. W. Marsh (4), M. B. Telfer (4) (Dudley); W. T. Cooper (5), J. A. Wildman (4) (Elbow Hill); W. Canny (1), E. P. Wall (0) (Eurelia); G. Ashby (3) (Farrell's Flat); M. M. Llewellyn (0), L. A. Dunn (6) (Finniss); P. W. Chittleborough (4), R. Holmes (3) (Frances); H. B. Scheer (0), L. Wachtel (0) (Frayville); K. F. Roediger (1), F. Wormald (2) (Gawler River); R. C. Jacob (5), R. F. Eylward (2) (Geranium); K. L. Blesing (4), J. S. Fisher (4) (Gladstone); B. A. Linke (4), F. Handtke (5) (Goode); C. Whillas (5), H. Reschke (6) (Green Patch); H. Helbig (5), H. Lange (6) (Greenock); R. J. Laing (1), I. E. Randall (3) (Gumeracha); T. E. Goodridge (4), A. Hermes (3) (Hanson); R. H. Cross (3), J. Brook (3) (Hartley); C. F. Kightley (4) (Hindmarsh Island); C. H. Fisher (5), S. Coad (5) (Hope Forest); A. Ridgway (5) (Wolseley); C. A. Newbon (3), F. L. Johnson (4) (Wudinna); E. A. Spriggs (0), A. Spriggs (0) (Yadnarie); G. P. Roe (5), T. L. Nottle (4) (Yaninee); G. W. Proctor (6), R. R. Wilson (5) (Yeelanna); H. M. McKenzie (5), G. R. Tregilgas (4) (Yurgo).

OPENING SESSION.

Congress was opened on Monday evening at 8 p.m. by His Excellency the Governor, Brigadier-General the Hon. Sir Alexander Hore-Ruthven, V.C., K.C.M.G., C.B., D.S.O. Mr. A. J. Cooke (Chairman of the Advisory Board of Agriculture) presided, and there were also present on the platform:—Hon. A. P. Blesing M.L.C. (Minister of Agriculture), Messrs. J. W. Sandford, A. L. McEwin, F. Coleman, H. N. Wicks, S. Shepherd, P. J. Bailly, P. H. Jones, Dr. A. E. V. Richardson (members Advisory Board of Agriculture), C. A. Loxton, B.V.Sc. (Chief Inspector of Stock), Dr. A. R. Callaghan (Principal Roseworthy Agricultural College), Dr. J. Davidson, Messrs. G. Samuel, M.Sc. (Waite Institute), W. L. Summers (Secretary Minister of Agriculture), W. J. Spafford (Deputy Director of Agriculture), G. Quinn (Chief Horticultural Instructor), C. F. Anderson (Government Poultry Expert), R. C. Scott (Supervisor Experimental Work), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary Agricultural Bureau).

THE GOVERNOR'S ADDRESS.

His Excellency said that there was no question as to the value of the Congresses of the Agricultural Bureau. One of the greatest handicaps the primary producer had to contend with, compared to those in the cities, was the difficulty of co-operation. They were so widely scattered that it was very seldom that they could come together and discuss their problems, and, as organised bodies, make their influence felt and their difficulties known.

It cannot be too often repeated that the rehabilitation of the primary producer and the restoration of his purchasing power are the most important things that must be done if national and world prosperity is to be revived, he added. Day by day, too, your task becomes more complicated and more technical. Not only have you to work your land, to think of soil and climate, but you have also to consider the question of economics, exchange, marketing, transport, and the cost of production. At the moment the question of marketing is the most prominent and difficult of all.

Efficient marketing makes the difference between the farmer getting a fair price for his produce and the man who handles the farmer's produce getting more than his share—the farmer getting a minimum result for a maximum of labor. Scientific marketing is a question that demands our very careful study. We know how successful the Danish farmers have been in marketing their produce, and we often ask ourselves, why? The Danish farmer is not a better man than ourselves, he has not any better soil, and his transport difficulties are great. But he has learnt the secret of marketing, of grading and producing his goods in an attractive form. And he has made one golden rule that nothing

but the very best under any conditions is allowed to leave his shores. He has also realised that one bad consignment will spoil his market and give his goods a bad name.

WORLD SUFFERING FROM MAL-DISTRIBUTION.

It has been suggested that the world to-day is suffering from over-production, but I think that we are gradually coming to the conclusion—and I think even our economists are more or less in agreement on this point—that it is not so much a question of over-production we are suffering from as mal-distribution. Scientific methods of production have outrun scientific methods of distribution. Science has brought about mass production, not only in our manufactured articles, but in our primary products and raw materials as well.

The soil can now produce far more than it ever could before. But unfortunately, at the same time, owing to various causes—hoarding of gold, fluctuating exchanges, and impenetrable tariff barriers—the arteries of distribution have become congested and choked, and the solution of the world's problems to-day lies in finding a means of clearing those arteries. It is a case of privation in the midst of plenty. A great deal of wealth of the world is lying idle, and at the same time there are millions of idle hands. The problem is to enable those idle hands to earn and circulate that idle wealth.

EASTERN MARKETS NEED EXPLOITING.

It has been suggested that production should mark time until distribution comes up into line with it. We have, I think very wisely, turned that down in this country. It was not feasible; it was not desirable; it was uneconomic. Moreover, one cannot say that there is over-production in the world until all the backward races enjoy the same luxuries and amenities of life as the more civilised communities. Civilisation is advancing by leaps and bounds. Science is cheapening production and placing our goods within reach of millions who were unable to procure them before.

In the old days we depicted the savage as arraying himself in a tall hat and a pair of spats, and nothing else, as the first sign of civilisation. To-day he is demanding a complete suit of the best cut and material, and the latest Paris fashion for his womenkind. We do not suppose that the Japanese, for instance, are going for ever to be contented to live in paper houses and eat rice as their staple food. But we must remember that other nations are alive to the awakening of the East just as much as we are. Geographically speaking, we are favorably situated. In our temperate climate we can produce goods which cannot be produced in the tropics, and at the same time we are in easy reach of those markets, compared with our rivals in Europe and other parts of the world.

MUST GO OUT AFTER TRADE.

But even these advantages will not last for ever. The methods of transportation and communication are also progressing and producers in every part of the world are being thrown into mutual competition, and that process is destined to grow. So we must not sit under the tree and wait for the fruit to fall into our lap. We must climb into the branches and help ourselves before others come along and select the best. The first man in gets the markets, and once in he is very hard to displace.

We must be careful in Australia not to become so absorbed in our local affairs that we lose sight of what is going on in the world outside, and miss our opportunities. We are somewhat out of the beaten track in a backwater, but the great tide of human progress goes rolling on all the time. Those who look ahead and read the signs correctly and sow the seeds in the early days are going to reap the harvest in the future.

My message to you to-night is to revive that pioneer spirit of the past and seek out fresh markets. Look beyond your own immediate neighbors. Let scientific development of your markets go hand in hand with scientific development of your land. There is an old song called "I Hear the East A-Calling." Let that refrain ring in our ears and stimulate us to renewed efforts in those undeveloped regions.

Dr. Richardson moved and Mr. Sandford seconded a vote of thanks to the Governor for opening the Congress.

THE MINISTER'S SPEECH.

The Hon. A. P. Blesing, M.L.C. (Minister of Agriculture) said:—In these times of economic stress it should be a matter of congratulation among us that this 44th Congress of the Agricultural Bureau should open under the auspices of relatively favorable weather conditions over the greater part of our agricultural areas. There was a time, during the opening months of the season, when crop prospects were far from satisfactory; to-day, however, subject to a continuance of favorable spring conditions, it is possible to anticipate a State crop yield above the average.

Unfortunately, from the economic aspect, prospects are hardly as pleasing. We are not yet out of the grip of those world factors that have made for low prices during the past six or seven years. With you, I rejoice in the recent improvement in the wool position. I trust that it may be but a foretaste of benefits to come, and that our great pastoral industry will know how to take full advantage of it; and may I add the hope that future successes may not make us forget the lessons of the immediate past.

It is regrettable that the prospects of better wheat prices for this season's harvest should not be as bright as those of wool. You all know the prominence recently given to wheat at the London World Economic Conference. It appeared at one time that because agreement appeared impossible on any single economic factor wheat was to be made the scapegoat for the failure of the Conference; and, judging from press statements, the fact that Australia's interests could not be brought into line with those of such countries as United States of America, Canada, Argentine, Russia, &c., it seemed as if Australia would have been asked to accept the position of the scapegoat for the failure not only of the wheat section of the Conference, but for the Conference as a whole.

We know that finally some sort of agreement has been patched up; and we hope that some good may ultimately come of it; but in what manner it is likely to raise the price of our 1933 wheat above the present low level it is exceedingly difficult to see, particularly as we know that the world carry-over of wheat from the immediately preceding season was abnormally large. In this connection, I shall state that the Government to which I have the honor to belong believes that the wheat farmer is entitled to costs of production at railway sidings; and should prices continue at their present low level, will take early steps to press upon the Commonwealth Government the necessity of finding adequate funds for assisting wheat farmers.

I congratulate you on the increase in the number of your country Branches. I notice that the number has risen from 316 in 1932 to 331 at the present time. I am an old Bureau member, and appreciate fully its advantages to our more or less isolated country producers; and you can rest assured that all your legitimate requests will receive my earnest and sympathetic consideration. I am very pleased to notice that out of 331 Branches, 38 are Women's Branches. No farmer can hope to succeed in his business without a competent wife, and the latter as much as her husband stands in need of exchange of ideas with others. The ideal to be kept before you should almost be "as many Women's Branches as there are Men's." In this manner efficiency in the home will be speedily reflected by corresponding efficiency on the farm.

WHEAT BREEDING.

The importance of wheat breeding to the State hardly needs emphasis at such a gathering as this, for all of you present at this Conference realise the value and necessity of a progressive programme of wheat breeding in a State such as ours, where wheat is the major primary product. Such a programme is being exploited to the fullest extent of the resources at our disposal at Roseworthy Agricultural College. That the wheat breeder's objectives in this work should be based on the soundest premises is of the utmost importance to the wheatgrower. Essentially the object of the breeder is to increase the monetary returns of the grower, and by the grower I do not mean the individual farmer so much as the farming community as a whole. It is possible to go on increasing the yield per acre at the expense of quality, but with the risk of losing prestige on the wheat markets of the world. The quality of our wheats must be given greater consideration in the future, and for this reason it is the policy of the College to aim at producing wheats of higher average quality than the low standards set by leading varieties, such as Nabawa and Free Gallipoli. It should be fully realised, however, that intrinsically high quality is not the object, for it is doubtful whether for our climatic conditions a wheat can be bred which will yield as well as our present standard varieties, and at the same time possess the quality of the best Canadian wheats, but wheats of better average milling value can be produced, and the object is to produce a wheat capable of yielding as well as, or better than, say, Nabawa, but of a superior milling quality. If a variety of higher yielding capacity is produced, but of lower flour strength, then the requirements of the State will not be met. The individual farmer may gain temporarily as a result of the immediate increase in yield per acre, but such a gain would be soon offset if the quality were below that expected of Australian wheat on the world's markets. I am pleased to be able to report that crosses were made at the College last season with this object in view, and by the use of a simple flour test, which can now be carried out on small quantities of grain, selections will be made from these crosses with the greatest confidence.

The matter of disease resistance is also receiving close attention, and varieties known to be resistant to certain diseases have been chosen for use as parents. Concisely, the aim of wheat breeding work at the College may be stated to aim at producing high yielding varieties, possessing good field characters, such as non-shattering tendencies and strong straw, as well as being of better quality and at last equal in disease resistance to our leading varieties of the present time. In recent years the New South Wales Department of Agriculture has pursued an extensive programme of wheat breeding, and during a recent visit to that State I was able to obtain small quantities of seed of some of their more promising new varieties, which are known to be of satisfactory milling quality. These varieties are at present being grown at the College, but while we can hope that varieties bred in other States will suit our soil and climatic conditions, it does not always follow that they will, for it is surely significant that the greatest proportion of the wheat grown in this State is of varieties bred by this State at Roseworthy College. Certainly this is true of outstanding crops. One need only scan the names of the varieties of winning crops in the wheat crop competitions to realise this, for Sword and Ford, two wheats bred at the College, have had pride of place in practically all cases.

It would seem that while we might adopt a comprehensive scheme of introduction of varieties bred by other States, that the best results would not accrue. Only by breeding varieties suitable to the particular climatic and soil conditions obtaining here can the best results be obtained, and for this reason we cannot, and must not, neglect our wheat breeding work. The gain from such work pays for it year after year by even the increase of one bushel per acre, and it would be a short-sighted policy, and one of false economy, to neglect such a national project.

Coupled with the wheat breeding work at the College is the systematic production of pure seed of the leading varieties at present commercially grown. The selection, multiplication, and re-multiplication of such seed, which requires very careful and conscientious attention, has been put on the soundest lines, and every possible precaution is being taken to prevent admixture of any description.

This work is well in hand, and it is confidently anticipated that reliable pure seed of the most important varieties will be regularly available in the future.

I notice that you have made provision for a special session on dairy matters, and in view of the recent progress in the industry, this is as it should be. Until quite recently we had been losing ground in dairying. Since 1929-30 our dairy cattle have increased by about 45,000 head, or nearly one-third; our butter production (21,000,000lbs. in 1932-33) has almost doubled; our cheese production (6,000,000lbs. in 1932-33) has also nearly doubled; our butter exports (9,500,000lbs. in 1932-33) have increased by nearly 9,000,000lbs. since 1929-30. No cheese was exported prior to 1931-32; in 1932-33 we exported 1,579,000lbs. You are, of course, aware that a Royal Commission was recently appointed to inquire into the dairying industry, and we hope that its report will soon be available. Its recommendations will receive our earnest consideration, and to the extent that we think feasible, will be adopted.

Progress in the poultry industry has also been outstanding of recent years. In this connection it will suffice to point out that whereas in 1930-31 we exported about 773,000doz. overseas, in 1932-33 our exports rose to about 3,841,000doz., or an increase of over 3,000,000doz.

Consideration of the progress that has been achieved of recent years in our rural industries must bring to mind the recent death of that old pioneer of progress, the late William Lowrie. To the younger generation among you he is perhaps no more than a name; but I am sure that there are many here to-night who had the privilege of listening to, and who have subsequently benefited by advice he gave in the nineties of last century. It is singularly appropriate that reference should be made to him at this Congress of the Agricultural Bureau. Mr. Lowrie was one of the original members of the Central Agricultural Bureau, and, until his recent demise, the last surviving member. The farming community as a whole owes a debt of gratitude to all those men, but in particular to Professor William Lowrie. What to-day forms part of the everyday routine of all successful farmers was a novelty in his day, and that this should be so you owe very largely to Lowrie's demonstration work and his skilful advocacy of improved methods. His name will always be linked with such progressive methods as the practice of tilled bare fallow before wheat; the use of superphosphate; the association of sheep with wheat in South Australia, &c. Nor should it be forgotten that, together with his predecessor (Professor Custance) he laid the foundations upon which the Roseworthy College has gradually developed. It can be said that with William Lowrie has passed away a man who foresaw the future possibilities of South Australian farming, and by his efforts induced the farming community gradually to follow the course which has led to modern achievements.

Reference to Roseworthy College reminds me of the recent appointment of Doctor A. R. Callaghan as Principal. He came to us from New South Wales with excellent qualifications. Doubt was expressed at the time as to the wisdom of the appointment of a man of his age to so important a position. He has now been with us for over twelve months, and it can be said that he has fulfilled the best hopes entertained of him. I hope that many farmers will send their sons to Roseworthy.

I trust that this Congress will rank among your most successful ones; and that you will return home determined to garner in a crop which will be not only useful to yourselves, but to the State as a whole.

THE CHAIRMAN'S REPORT.

The following report on the activities of the Advisory Board during the past year was read by Mr. A. J. Cooke:—

The past year has been one of the busiest periods which the Board has experienced for many years. Careful consideration has been given to a large number of resolutions, proposals, and suggestions made to the Board, and wherever there were opportunities of meeting the wishes of Branches, efforts were made to seek concessions or assistance in the best interests of the primary producer.

The main difficulty to contend with during times like the present is that of Government finance. In fact, in some instances this has been the only stumbling block barring the way to the successful attainment of requests submitted to the Government. Such requests, however, have not been lost sight of, as it is the policy of the Board to review them from time to time, so that when favorable opportunities present themselves further representation will be made in order to place before the Government reasonable avenues by which assistance can be given to the farming community.

The resolutions submitted by Congress, Conferences, and Branches dealt with a wide range of subjects, and I propose to outline briefly what has taken place on these matters since we met 12 months ago.

At last year's Congress an urgent request was made for an investigation into mammitis in cattle. I have pleasure in reporting that steps have been taken by the Australian Dairy Cattle Research Association to investigate this disease, as well as contagious abortion and other diseases affecting cattle. This work is being conducted in New South Wales and Victoria, and the Association is in active co-operation with its branch in South Australia.

In connection with railway matters, attention was drawn to the necessity for the careful handling of cans of cream at stations and sidings, and during the year rail freights on wheat, livestock, and wool have been reduced by 20 per cent. of the previous rates.

Representations were made to superphosphate manufacturers for a reduction in price, and it is pleasing to note that public announcements have been made to the effect that reductions have recently been made. While speaking on this question, I would like to remind our members that users of fertilisers for purposes other than wheat-growing may secure from the Federal Government an allowance of 15s. per ton during the year ending November 30th next.

In respect to the Farmers Relief Act, measures were taken by the Government to extend the operations of the Act so that farmers may obtain finance to pay for such items as Life and Fire Insurances, Clothing, Medical Expenses, Subscriptions to Friendly Societies, Machinery, Fencing Wire, Stallion Fees, Subscriptions to Veterinary Lodges, Veterinary Services, and Rabbit Poison.

The question of purchasing stallions through the State is one matter which is to be again brought under the notice of the Board for further consideration.

The conditions under which farmers were working in relation to transport of their produce—and which were brought before last year's Congress—have been materially altered in as much as primary producers may use commercial vehicles for purposes other than the carriage of goods for hire or reward and further, a large number of permits for the carriage of primary products—including lambs, calves, and pigs—over various roads of the State have been granted by the Transport Board.

Special representation was made to the Government during the year for better facilities in connection with veterinary services. Many members here to-night will remember the popular lectures and demonstrations given by the late Dr. Place, and there have been continual requests by Branches for similar lectures. We have been indebted to the Chief Inspector of Stock and the Principal of the Agricultural

College for the assistance they have rendered from time to time, but they have not been able to meet the constant demand which Branches have made. On this account the Board interviewed the Minister, and made suggestions so that the Department of Agriculture would have the part-time services of a veterinary surgeon to visit Bureaux and Conferences. Owing to the financial position, however, the Government have been unable to accede to the request for the present, and the Minister has asked that the matter be referred to him again during the early months of next year. In the meantime a Committee of the Board has been appointed to investigate the matter so that full information will be available for the Government when the question is re-submitted.

Efforts have been made to secure alterations to the tariff on fertilisers. There has not been any favorable result. During the year, however, two members of the Board gave evidence before the Tariff Board with the object of securing an alteration in the existing duty on sulphate of ammonia.

A new rule has been adopted in connection with the publication of the Congress Report, whereby the number of attendance cards handed in by each delegate is published in the *Journal*.

Enquiries were made in connection with the increased price of American farm journals, and it was found that the extra cost was due mainly to exchange, and consequently the Board could not take this matter any further.

The Director of Education informed us that with reference to the resolution passed at the Women's Congress asking that first aid be taught in schools, this subject was taught wherever possible. All trainees at the Teachers' College are instructed in first aid, and every year there is an increasing number of schools in which the subject is taught.

In connection with the operations of the Society for Prevention of Cruelty to Animals, Branches were informed that they may take whatever action each Branch though fit to protect their members wherever it was thought such protection was necessary.

Special legislation was not deemed necessary in the case of having the grade and guarantee of purity of contents marked on containers of lubricating oils and greases. Where there is competition among vendors of goods of this kind ordinary trade relationship as between the buyer and seller was deemed sufficient for the regulation of the quality of the goods.

In connection with the destruction of rabbits on Crown lands in farming areas, assistance has been given to district councils as far as Government funds have permitted for the purpose of destroying rabbits after sections have been declared vermin infested. This matter will, however, receive the attention of the Congress again this year.

Owing to unforeseen circumstances in connection with the calling of this year's Congress, it is regretted that we were unable to send the agenda to Branches earlier. As soon as approval to hold the Congress was given, however, Branches were notified, and when sufficient material had been supplied the Congress Committee met to consider motions, &c., submitted. While this was in progress the Committee were able to arrange a programme of addresses, &c., which will, I feel sure, maintain the high educational standard which has characterised our Congress for so many years. Our greatest thanks are due to the assistance which contributors have given to us in arranging an agenda at short notice.

Owing to the fact that wheat crops judged in the championship competition are those awarded first place in their respective districts and not from the whole of the competitions, it is not equitable to give special recognition by means of trophies to crops placed second and third among the championship entries.

Orchardists will be pleased to learn that the services of Mr. Geo. Quinn, Chief Horticultural Instructor, have been retained, and the Minister has been approached by the Board with a proposal which, if adopted, would mean that more time could be given to the compilation of the records of the Blackwood Experimental Orchard. This matter is at present under consideration.

Precautions against outbreak of fires through the medium of internal combustion engines in the fields were discussed at the Gladstone Conference, and the Minister has intimated that a section in the amendments to the Bush Fires Act will be added to deal with the use of portable engines in the open.

Representation has been made to the Government for a Pure Seeds Act which was recommended by Conferences, and the Board hopes that some such legislation will be enacted to give protection to producers when purchasing their seed requirements.

Irrigation problems along the River Murray have received the attention of the Board, and effect has been given to the request of Branches that more frequent irrigations be made available to the River Murray settlers. The Bureau Conference at Berri expressed the view that lighter waterings are desirable in order to assist in combating the increased salt and seepage trouble, and Branches have been asked to give this matter their earnest attention.

The rising water-table on the Berri Flat is causing settlers in that area considerable anxiety, and a request was made to the Waite Agricultural Research Institute for an investigation in order to ascertain if the cause is wholly or in part attributable to the general rising of the level of the river consequent on the construction of the locks and weirs along the Murray. Professor Richardson has intimated that a report will be made available to the Board in terms of this request.

The system of irrigation along the River Murray came up for discussion at the Berri Conference, and the Board has made a request to the Department of Lands to consider the possibility of modifying the present system in order to conform to the suggestions made in a pamphlet issued by the Council for Scientific and Industrial Research.

In connection with the proposal to centralise the control of the lower swamps of the river at Murray Bridge, the Board has made a request to the Government that the person appointed to the administrative position should be one with a thorough knowledge of agricultural irrigation.

Attention was drawn to the spread of cape tulip in the south-eastern portions of the State, and at the request of the Board the Local Government Department made an appeal to the district councils to have this weed destroyed as early as possible.

The Dairy Conference at Mount Barker recommended that all factories be compelled to pay for cream according to grade on a differential basis. The Minister has asked that this matter be placed before him again after the Dairy Commission has presented its report, so that he can give consideration as to amendments which are necessary to the Dairy Industry Act and suggested alterations to the existing regulations. When this report is received, the Board will have an opportunity of reviewing other items which have come before it in connection with the dairy industry.

The Board was represented on the Committee which was appointed to make an investigation into the question of the adjustment of debts. It is understood that an amending Bill is being prepared as a result of the work of that Committee.

At the request of the Non-irrigated Fruitgrowers' Conference, arrangements have been made whereby apple growers may have their sizing gauges tested by officers of the Department, and cultivation tests to determine the effect of deep cultivation in apple and stone fruit orchards are being arranged for trial at the Blackwood Experimental Orchard. Experiments are also being conducted at Angaston with the layering of vines with the object of re-organising old, worn-out vineyards.

The importance of the work done at the Blackwood Experimental Orchard is fully recognised by the Board. Representation has been made to the Minister to have the vacancy of Orchard Assistant filled, and it is hoped that this appointment will be made with the object of maintaining the valuable assistance which this institution offers to the fruitgrowers of the State.

A request was made from Branches that a scheme of certification of potato seed be adopted so that growers might be in a position to obtain reliable seed within our own State. A conference was held at Mount Barker, and approval was subsequently given by the Minister to the proposals outlined by growers of seed at that meeting.

The number of Branches has been increased, and it is pleasing to be able to state that despite the period of depression there has not, on the whole, been much lack of application of the main objects of our organisation. The Bureau exists mainly for educational reasons, and this objective is achieved by the mutual assistance which one member is able to give to another, and by close contact with the technical officers of the Department. So long as farmers realise the educational advantages which this institution affords we have no fear as to our future, and we will continue to exist for the benefit of the primary producers, and make that progress which has been an outstanding feature of the work of the Bureau for the past 45 years.

Throughout the year Conferences have been well attended, and representatives of Branches have shown a general desire to assist these meetings by reading papers and by helping in discussions on matters of importance and interest to their districts.

At last year's Congress and at subsequent Conferences, resolutions were passed with reference to the annual subscription of 2s. 6d. The main objection to the existing conditions seems to be the discrimination between old members and new members, and the Board is of opinion that a flat rate charge of 2s. per household, exempting life members and Branch Secretaries, would be preferable to the existing arrangement. There is a motion on the agenda dealing with the subscription, and an opportunity will then be given to discuss the matter further.

Other features of Bureau work, such as competitions and various meetings of a social nature, have not been neglected. Every district should have its competition whether it be for crop growing, pruning, or any other form of rural activity, and in particular I appeal to farmers in the wheat-growing areas to renew their support in the crop competitions to an extent which will outrun even the record years since the championship competitions began.

Special meetings will be held at this Congress for delegates from Women's Branches. There are 38 of these Branches having an important influence on the social work of the districts in which they are formed. The Department of Agriculture is lacking in a staff appointment directly applicable to the work of women members of the Bureau. Assistance in this respect comes from outside, and the Board wishes to extend our thanks to Miss Campbell, of the Education Department, for her continued assistance in preparing and giving addresses to Conferences and Branches wherever it is convenient for her to attend. This work is all the more appreciated when it is remembered that her services are given voluntarily, and are consequently the outcome of a genuine desire to assist the movement. Valuable work is also accomplished by individual members of Branches who have given such practical support from year to year to their Branch meetings, Congress, and Conferences throughout the State.

The Agricultural Bureau appreciates also its association with the officers of the Department of Agriculture. It may be said that were it not for the agricultural Bureau these officers would find it difficult to get in such close touch with the farming community. This is undoubtedly true, but on the other hand we feel that we have a staff intensely interested in their work, competent to perform it, and furthermore willing to sacrifice personal convenience in a desire to further the interests of those whom they are appointed to serve. The untiring efforts of the Director of Agriculture (Professor Perkins) in his services for the benefit of the primary producer are well known to us all. Besides the big task of controlling his Department we find him a guiding hand at our meetings, and we are looking forward with

considerable interest to the final reports of the Bulk Handling Committee and the Dairy Commission, on both of which he so ably represents the Department as well as the farming and dairying interests of the State. Similarly, Messrs. W. J. Spafford, Geo. Quinn, H. B. Barlow, C. F. Anderson, R. C. Scott, and the able officers working under them, have accomplished much for the benefit of primary production, and I feel sure that I voice the sentiments of Bureau members generally when I state that given proper facilities for their work they will continue to render that service which has been distinguished by their efforts in the past. Outside of the department the Agricultural Bureau has received the assistance of private lecturers, &c., as well as the help of the Stock and Brands Department and the School of Mines. The work they have done for us is regarded very highly by our Branches and we extend to them our appreciation of the manner in which they have shown their willingness to co-operate with the department whenever possible.

In closing, I would like to pay a tribute to the work of our Branch Secretaries who act as the principal executive officers of the organisation in their respective districts. Their work is often onerous and perhaps at times irksome, but they prove themselves loyal to the organisation by sustained interest in its affairs, and by exhibiting a high sense of duty in the voluntary work which they undertake for the good of their fellow members.

TUESDAY, SEPTEMBER 12th.

Morning Session.

Mr. H. B. BARLOW (Chief Dairy Instructor) delivered an address, "The Production of Pigs Suitable for the Local and Export Markets."

Mr. W. N. RULE (Butter Grader and Factory Inspector) read a paper, "The Care of Milk and Cream on the Farm." (This paper was published in the September issue.)

"Egg Production on the Farm," by Mr. F. Wormald (Gawler River). (This paper appears in this issue.)

The following resolutions were then carried:—

That no points be deducted by Judges at the Royal and other Agricultural Shows for dehorned bulls, and that the Government be asked to introduce a law making it compulsory for all bulls to be dehorned.

That this Congress request the Government to introduce legislation to provide for a Cattle Compensation Fund on similar lines to that carried out in Victoria.

At the Horticultural Session the following papers were read and discussed:—"Experiments in the Steaming of Figs," Mr. N. S. Fotheringham, R.D.A. (Manager Berri Experimental Orchard); "Orange Survey on Irrigation Areas" (this was published in the September issue). Mr. E. F. Ward's (Stanley Flat) paper on "Salient Points in the Preservation of Fruit" is published in this issue.

Afternoon Session.

Papers as follows were read:—"The Lucerne Flea Problem in South Australia," Dr. J. Davidson, M.Sc. (Waite Inst.); "The Meat Export Trade," Mr. H. J. Copley (Chairman Stock Salesmen's Association); and "Resume of 12 Years Experimental Work at Kybybolite," Mr. L. J. Cook, R.D.A. (Manager Kybybolite Experimental Farm).

Evening Session.

Mr. W. J. Spafford (Deputy Director of Agriculture) addressed delegates on the "Diseases Responsible for the Reduced Wheat Yield in 1932," and Mr. C. T. McKenna, B.V.Sc., M.R.C.V.S., read a paper, "Two Diseases of Sheep of Economic Importance in South Australia."

WEDNESDAY MORNING, SEPTEMBER 14th.**FREE PARLIAMENT.**

The following resolutions were carried:—

"That owing to the fall in the price of petrol a deputation of members of the Advisory Board wait on the major oil companies asking for a substantial reduction in the price of power kerosene."

"That Congress urge the Federal Government to abolish the duty on kerosene and reduce the duty on petrol by 50 per cent., and that letters to this effect be sent to the Prime Minister, the Minister of Customs, and each member from this State."

"That Congress approach the super manufacturers with a view to obtaining a reduction in the price of superphosphates."

"That the Federal Government be approached to form a Home Consumption Pool at a price sufficient to bring the total harvest to the average price of 3s. 6d. per bushel."

"That the Government be urged to sanction the putting into effect some system of bulk handling of wheat in South Australia to benefit producers."

"That Congress approach the Government with a view to their abolishing the unconstitutional Act which provides or demands that a farmer sell his wheat after a period of 90 days."

"That Congress requests the State Bank, when sending out Form D.2, which shows the allocation of crop proceeds, to definitely state how much interest is paid and to whom paid. The information is required for income tax returns."

"That Congress urge the Government to have appointed more representatives of farmers on the Farm Relief Board."

"That Congress ask the Government to empower the Farm Relief Board to provide accommodation for farmers under the Farm Relief Act to pay a subscription to district hospitals."

"That in the case of a bush fire, where serious damage is done to property, the aggrieved owner shall have the right to demand an inquest without financial liability."

"That an appeal be made to the Government to destroy rabbits on Crown lands."

"That the Government supply to landholders all poison free for the destruction of rabbits on adjacent unoccupied Crown lands and roads."

"That a double fence be put around roadway, railway and all boundary fences of isolated paddocks if the condemned pleuro paddocks adjoin the roads."

"That this Congress requests that the Government be asked to appoint a permanent instructor on sheep, lambs, and wool to the agricultural staff."

"That in view of hard times at present prevailing amongst outback farmers, a special concession be granted by executive of Royal Show, Adelaide, that they be allowed to send in entries for competition at Royal Show at a nominal rate instead of having to take out a full member's ticket."

Congress supported the proposal of the Board in recommending an annual household subscription of 2s. for the *Journal of Agriculture*, the present exemptions to remain.

"That this Congress of delegates assembled from various parts of the State is alarmed at the Government's notification that certain concessions enjoyed by delegates of the Agricultural Bureau for the past 44 Congresses are to be curtailed, and respectfully ask that the Government reconsider the matter with a view to having future Congresses arranged under the same conditions as in the past. South Australia is essentially dependent on the success of primary production and we are strongly of the opinion that Congresses are of immense benefit to producers throughout the State, and that the proposed action will react detrimentally to the Agricultural Bureau system."

DEFEATED MOTIONS.

"That the following taxes and Customs duty be abolished on the undermentioned items used by primary producers:—Sales tax on all lubricating oils and greases and Customs duty on all fuels for tractor and transport vehicles."

"That the Advisory Board of Agriculture be empowered to fix the f.a.q. standard of wheat in South Australia."

"That further representations be made to the Government to allow grain to be conveyed in washed superphosphate bags."

"That a time limit be placed on the discussion on all papers read at Congress."

"That the procedure of the Annual Congress be altered, the Free Parliament session to be extended and to take precedence of all papers."

LAPSED MOTION.

"That the Stallion Act be amended."

MOTIONS WITHDRAWN.

"That at least five minutes be allowed the mover of motions and resolutions when introducing the same."

"That as apparently the rule *re* new members is not giving satisfaction, it be rescinded, and the following substituted:—"That all members, except life members and Branch Secretaries, pay the annual subscription of 1s. if they do not require the *Journal*, or 2s. 6d. including the *Journal*. Members whose subscriptions are unpaid on January 31st be struck off.'"

Evening Session.

The following addresses were delivered:—"With the Trade Ship to the Near East," Mr. J. B. Murdoch (Member Advisory Board), and "Farm Implements and Machinery" (illustrated), Mr. S. Shepherd (Member Advisory Board).

On Thursday morning delegates inspected the Waite Research Institute at Glen Osmond.

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board was held on Wednesday, August 30th, there being present Messrs. A. J. Cooke (Chairman), A. M. Dawkins, J. B. Murdoch, S. Shepherd, A. L. McEwin, Geo. Jeffrey, F. Coleman, P. J. Baily, H. N. Wicks, J. W. Sandford, Professor A. J. Perkins (Director of Agriculture), and Mr. H. C. Pritchard (Secretary). An apology was received from Dr. A. E. V. Richardson.

Re-appointment of Members.—The Honorable the Minister intimated that he had re-appointed the following as members of the Board for two years from July 1st, 1933:—Messrs. R. H. Martin, J. W. Sandford, S. Shepherd, A. L. McEwin, J. B. Murdoch, Geo. Jeffrey, and Dr. A. E. V. Richardson.

Annual Congress.—The Secretary intimated that arrangements had been finalised for the 44th Annual Congress to be held in the Way Hall on September 11th to 13th. His Excellency the Governor would deliver the opening address at 8 p.m.

Life Members.—The following names were added to the roll of Life Members of the Agricultural Bureau:—Mr. J. Turner and Mr. S. W. Chapman (Blackwood), Mr. John Boundy (Minlaton), Mr. W. L. Schulz (Petina), Mr. P. R. Hodge (Taplan), and Mr. W. Giles (Angaston).

New Branches.—Approval was obtained for the formation of Women's Branches at O'Loughlin and Wepowie, with the following persons as foundation members:—*O'Loughlin*—Mrs. G. W. Foggo, Miss G. Foggo, Mrs. J. S. Foggo, Mrs. S. Trewartha, Miss G. Trewartha, Miss E. Trewartha, Miss D. Kloeden, Mrs. A. Kloeden, Mrs. E. E. Lutz, Miss F. Hasting, Mrs. C. Bergmann, Miss V. Kloeden, Mrs. W. V. Pfeiffer, Mrs. A. W. Pfeiffer. *Wepowie*—Mesdames J. F. Burns, L. R. Jasper, M. B. Duffy, L. Kitto, R. M. Orrock, H. W. Noske, and L. H. Pasco, Misses A. Noske, J. Medlow, D. L. Gregurke, J. Gregurke, G. M. Halliday, E. H. Roocke, A. Knauerhase, V. Roocke, and B. Roocke, and Mrs. A. B. Knauerhase.

New Members.—The following names were added to the rolls of existing Branches:—Angaston—Sibley Russell; Kalangadoo Women's—Mrs. J. Hunt; Mangalo—F. Munday, A. Hannemann; Paruna—W. E. R. Sumner; Morchard Women's—Mrs. Halliday, sen.; Brownlow—N. Brook, C. G. Brook, M. O. Steinborner; Truro—J. Steinert, C. Steinert; Oalca—D. Oash; Butler—N. W. Wayre; Pinnaroo Women's—Mrs. W. J. Eley, Mrs. E. Staker, sen., Mrs. G. E. Harding, Mrs. H. K. Harding, Mrs. J. B. Webb; Eurelia—A. Hall; Yurgo—M. C. Rogers, O. C. H. Easton, L. S. Hopgood; Eurelia Women's—Miss Hall; Coonawarra Women's—Mrs. F. Jackson, Mrs. L. Teichelman; Rosedale—E. Mellors, W. Myers, N. J. Webb; Goode Women's—Miss D. Jolly; Pinbong—A. L. Berry; Lone Pine—H. Parbs, A. Liebich, J. H. Schultz; Port Elliot—E. H. Coote, L. Ifould; Blyth—J. Strout, R. Lilywhite, R. Coles, R. L. Gold; Gladstone Women's—Mrs. V. C. Woods, Mrs. D. Prior, Mrs. J. Leesue; Balumbah Women's—Miss R. Strelan, Mrs. J. Murphy; McLaren Flat—R. G. Nottage; Strathalbyn—Sergt. A. Kite, W. P. Merten, K. V. Griffin; O'Loughlin—G. W. Foggo, J. S. Foggo, S. Trewartha, C. Kloeden, W. Lutze, D. Trewartha, A. Trewartha, W. Foggo, E. Foggo, A. Kloeden, jun., C. Griffen, W. Kloeden, P. Zacharzewski; Tantanoola—C. McPherson, R. Mundy; Myponga—J. Bowyer, E. H. Baxter, H. Lawton, F. Summers; Wirrilla—R. Tickle, V. Ratlew, R. Kelly, — Collins; Boor's Plains—M. Ward; Sutherlands—G. W. Kernich, L. C. Kernich; Block E—R. Francis, G. Francis, A. W. Lott, J. Haynes, D. Winder, F. C. Berrill, Mrs. E. Harris; Greenock—C. B. Schultz, O. Nitschke, L. Ottó, G. Jenke, B. Bahnisch; Parilla Women's—Mrs. L. G. Martlew; Black Springs—J. Fisher; Kangarilla Women's—Miss H. Paddick, Miss Yvonne Myer, Mrs. L. Osmond, Mrs. S. Dowling, Mrs. K. Grimwood; Clare Women's—Mrs. A. Telfer, Mrs. L. A. Davies, Mrs. G. Bails, Mrs. A. C. Pollock; Belalie Women's—Mrs. O. Brogan, Mrs. F. Hockey; Maltee—N. Bayley; Balhannah—W. Miller, W. Hicks, H. H. Shillabeer, C. Dibel, P. J. Nolan, W. A. Robinson, A. G. Middleton, R. Hancock, G. R. Cowell; Kelly—L. Smallacombe, T. S. Cheeseman; Monarto South—A. H. Schubert, O. Beschke, H. T. Braendler, B. E. Hein; McLaren Flat Women's—Mrs. J. Sigston, Mrs. S. Ward;

Rendelsham Women's—Mrs. M. Klem, Mrs. C. Osmond; Moorook—S. Perkins; Barmera—F. C. L. Cook, E. Anderson, J. B. Cockin, E. Wiedeman, W. Mudge, C. Pike, L. Wing, Milang—J. Daniels, L. Young, G. Vaughton, J. P. Yelland; Kulkawirra—J. Guthleben; Frances—F. A. Stevens; Light's Pass—E. Hahn, B. Semmler; South Kilkerran—L. E. Jacka, E. F. Heinrich; Boolgun—N. Koehne; Mypolonga—H. O. Rowley, H. Lawson, R. R. Rowcroft; Millicent Women's—Mrs. L. R. Elton; East Allendale—N. C. Wallace; Artherton—W. H. Bagshaw; Hope Forest—L. Fincher, R. Coad, C. Peterson, Mrs. E. Peterson; Berri—W. J. Kitson; Nunkeri—R. Bruce, J. Ling; Petina—D. J. Aiston, B. Mudge; Wilmington—Dr. G. J. Stoney, P. H. Spaegth, L. G. Pascoe; Wolseley—M. B. Steer, F. J. Sherwell, F. J. Tregoweth; Millicent Women's—Mrs. G. B. Hutchesson, Miss K. M. Hutchesson, Miss I. Fensom; Dudley—W. M. Roach, J. W. Marsh, L. Longbottom, R. Hyde, M. Hyde, E. G. Spackman, D. Ritchie, A. Champ, L. Seipelt; Weavers—R. Daniell, A. C. Cornish, J. Purvis, jun.; Parilla—J. W. D. Carman; Finnis—M. Squires, J. Byrnes; Nunkeri—H. W. Sanders; Belalie Women's—Mrs. D. Boucaut, Mrs. L. Boys, Mrs. P. J. McCarthy, Mrs. E. E. Grabra, Mrs. W. Hoffmann, Mrs. — Davies, Mrs. H. Medlin, Mrs. — Honey, Mrs. E. E. Bayly; Pinnaroo—C. Dowd, L. Dowd, A. Davis; Lyndoch—W. Hutchinson, F. H. Springbett; Warrambo Women's—Miss D. L. Oswald, Miss M. L. Dolphin; Stockport—H. Arnold; Blackwood—G. Morphett; Mount Gambier—S. R. Ricketts; Butler—C. S. Coleman, C. E. Reynolds, H. B. Tilly, R. Coleman, W. Davey; Kybybolite—F. C. Watson, R. J. Pettit, J. D. McAuliffe, L. Darcy, P. Edwards; Myponga—T. D. Coward, S. Herring; Lenswood and Forest Range—E. Mason; Goode—E. Morecombe, C. Townsend, W. Lange; Mundalla Women's—Sister G. G. Morphett; Belvidere—Master J. Vivian; Taplan—J. B. Scheadel, J. Lintern, J. Neaylon, W. Fogden, M. Fogden, W. Laidlaw, A. Jenkins, A. Wallis, P. Bates, R. Chellew; Bute—H. Percy, S. P. Wheaton, Dr. C. T. Pfeiffer, S. Heinrich, C. Measday, K. Hall; Taplan Women's—Mrs. B. Rayson, Mrs. E. H. Schulze, Mrs. P. Burridge, Miss Gogler, Miss I. Hammond, Miss V. Hammond, Miss N. Rayson; Cummins—R. Granit; Morehard Women's—Miss B. Halliday, Miss S. Twigden, Miss D. Twigden, Miss R. Twigden; Netherton—W. J. Wilkin; Laura Bay Women's—Miss A. Lowe, Mrs. E. D. Barnett, Miss V. Barnett, Miss T. Barnett, Miss M. Spry; Mount Barker—W. Bell; Yurgo Women's—Mrs. J. Jarrett, Miss B. Jarrett, Miss N. Jarrett, Mrs. R. Rogers, Mrs. V. Easton, Mrs. N. Easton.

Present number of members, 7,785; present number of Branches, 331.

The Board considered a number of items in Committee.

GRUBBING

IS A ONE MAN JOB

FOR STUMPS LARGE OR SMALL, GREEN OR DRY,
SHORT OR HEAD-HIGH. THE ENORMOUS POWER OF A

MONKEY GRUBBER

EASILY ACCOMPLISHES THE TASK

Removing the most stubborn obstacles cleanly, with most roots intact.
Easy to handle, simple to operate, expeditious—its only need, regular oiling.
The Standard equipment will clean up everything over 1½ acres from one anchorage.

Each part designed for simplicity, easy handling and long trouble-free service.

DAIRY AND FARM PRODUCE MARKETS.

MESSRS. A. W. SANDFORD & Co., LIMITED, reported on October 2nd, 1933:—

BUTTER.—With the bountiful spring rains received the production of dairy produce expanded very rapidly last month and a good deal of the leeway was made up as a result of the dry June and July. Although the export of butter this season is still considerably below last year's exports, the disparity is now being lessened each week because of the increased productivity in South Australia. Fortunately the British market showed improvement, and prices hardened there, but at the date of report values were slightly easier again. The local trade has been well maintained, so that ready clearances have been effected of all butter from week to week. Choicest creamery fresh butter in bulk, 1s. 2½d.; prints and delivery extra. (These prices are subject to the stabilization levies.) Store and collectors', 8d. to 8½d. per lb. at store door, less usual selling charges.

EGGS.—Packing for export is now in full swing, but there is a large proportion of the supplies from country districts which will not pass the graders, and for these there is not nearly so strong a demand as for the prime quality new laid export eggs. Farmers can assist the industry greatly by taking more care with their supplies and having them marketed promptly and by keeping them clean, and this all helps to enable shippers to get larger numbers away. Ordinary country eggs, hen or duck, 4½d. per dozen.; selected export quality eggs, 1½ozs. and over, 8½d. to 9½d. per dozen.

CHEESE.—This commodity is being manufactured in larger quantities each week, and from now on exporting will be done to relieve the position. Local and Western Australian trade, however, is keeping up well, but is now not sufficient to absorb all stocks. New makes, medium and large, 7½d. to 7¾d.; loaf, 7½d. to 8½d.; semi-matured and matured, 9½d. to 10d. per lb.

BACON.—The trade in bacon continued at a high level throughout September, the cool weather having assisted in this respect. Considerable business was done in forward booking of Christmas hams, and the trade is in a sound condition, and stocks have been kept moving nicely from week to week. Best local sides, 9½d. to 9¾d.; best factory-cured middles, 10½d. to 11d.; large, 9d.; rolls, 8d. to 8½d.; hams, 11d. to 1s. per lb.; cooked, 1s. 1d. to 1s. 2d.

LARD was somewhat short in supply and the market was firm. Print lard, 7s. per dozen.

ALMONDS.—Moderate supplies were received on to the clearing floors each week, and these met with ready quittance at quotations. Softshells and Brandis, 8½d. to 9½d.; hardshells, 5d. to 5½d.; kernels, 1s. 11d. to 1s. 11½d. per lb.

HONEY.—A better demand for honey set in at the beginning of the month, and some interstate sales and good local trade was negotiated. Stocks held have been considerably reduced, and preparations are now being made for the handling of the new season's flow. Prime clear extracted in liquid condition, 3d. to 3½d. per lb.; lower grades, 1½d. to 2½d. per lb.

BEESEX.—Stocks are light and demand moderate. 1s. 0½d. to 1s. 2d. per lb. according to sample.

LIVE POULTRY.—Supplies throughout September were rather lighter than usual, but this no doubt would be due to many farmers visiting the city for the Adelaide Show, and also the cold wet weather interfering in some districts with deliveries. Values ruled firmer and a strong demand was experienced for all classes of poultry. We advise consigning. Crates loaned on application. Prime roosters, 4s. 3d. to 5s.; nice-conditioned cockerels, 3s. 6d. to 4s. 2d.; fair-conditioned cockerels, 2s. 9d. to 3s. 4d.; chickens lower. Heavy weight hens, 3s. to 3s. 10d.; medium hens, 2s. 6d. to 2s. 10d.; light hens, 2s. 2d. to 2s. 5d.; couple of pens of weedy sorts lower. Geese, 3s. to 4s. 6d.; goslings lower. Prime young Muscovy drakes, 4s. to 5s. 3d.; young Muscovy ducks, 2s. 10d. to 3s. 4d.; ordinary ducks, 1s. 9d. to 2s. 9d.; ducklings lower. Turkeys, good to prime condition, 8½d. to 1s. per lb. live weight; turkeys, fair condition, 7d. to 8d. per lb. live weight; turkeys, poor and crooked breasted lower. Pigeons, 4½d. to 6d. each.

POTATOES.—Local new, 4s. 9d. per cwt.

ONIONS.—New season's, 4s. per cwt.

RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall at the subjoined stations for the month of, and to the end of September, 1933, also the average precipitation for September, and the average annual rainfall.

Station.	For Sept. 1933.	Av'ge for Sept.	Av'ge Annual Rain- fall.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[Branch Secretaries are reminded that the following are exempt from payment of the Annual Bureau subscription:—Life members, Branch Secretaries, members appointed before August 1st, 1930, and new members who reside in the same house as (a) a life member, (b) Secretary, or (c) another member who already subscribes.

The subscription for all other members is 2s. 6d., commencing from August 1st in each year, provided that—subject to the above exemptions—nominations forwarded during the months of January to June must be accompanied by a payment of 1s. 6d. each nomination for that period.]

July 7th.—Attendance, 10.

SHOEING HORSES ON THE FARM.—Mr. H. Kupke read the following paper:—"When travelling about, one often sees working horses on farms that have a stiff and hobble gait, look poor, with rough coats, and have a jaded appearance. By looking closer one often finds that this is not for want of feeding and care, but if these horses had shoes on their feet they would probably look the best horses on the farm. If horses working on stony farms require shoeing, it pays well for the time lost in fitting them with shoes, especially at harvest time, wheat carting and seeding. They travel much better, and will not lose condition, as the unshod horse doing the same kind of work. There are many draught horses that are faulty in the hoofs; therefore farmers should be very careful to breed from mares and sires that have sound, round feet that are free from cracks and splits, and also wide heels. Shoeing can be done by most men on the farm who are sufficiently strong to hold up the horses' legs. First, take off the unevenness to make the hoof level (be careful not to interfere with the frog, excepting to remove any loose pieces); then start fitting the shoes so that they will lay perfectly on the foot, and the outer edges of the shoe just level with the walls of the hoof. Have the heels about $\frac{1}{2}$ in. wide each side, but not too long, because it is likely that some horses in over-reaching may pull off the shoes. Punch holes so that the nails will fit well and clip the shoe neatly. Commence nailing. Be careful to set all the nails at the same angle so that they will come through evenly. In driving the nail, give 2 light taps, then send home with 4 or 5 sharp hits. Cut off the points close with a farrier's shoeing hammer. When all the nails are driven draw up in the usual way. When clenching the nails the foot should be level on the ground; this will allow the shoe to slacken a little, and there will be a springing effect on the shoes. Finish off with the shoeing rasp, but keep the rasp off the clenches. Use the very best make of nails for draught horses—No. 8 and 9 nails. Shoes should not be too heavy, $\frac{1}{2}$ in. x $\frac{1}{2}$ in. mild steel are preferred. When the shoes are on give the hoof a painting of Stockholm tar, or an oil that is cooling (Neatsfoot), &c. (Secretary, H. McCallum.)

June 19th.—Attendance, 12.

MAKING A WILL.—The following paper was read by Mr. A. Watke:—It is said that a man's first duty to his dependants is to make the best possible provision for their present and future needs. He cannot properly safeguard their future unless he makes a good will. He opens the way to confusion and unhappiness if he waits until he is ill. He who is wise then will avoid mistakes by making his will while in good health. A will is a written document giving instructions for the disposal of one's effects after death. It is naturally a most important document and one which should be properly prepared by a competent person, such as a solicitor or a reliable Executor Company, so that future difficulties in interpretation, or cost in obtaining the Court's decision as to meaning, may be avoided. It must be signed, witnessed, dated, be without alteration unless properly initialled, and should be the only document of its kind left existent by the testator. The necessity for a will is the proper allocation of a person's effects after death according to his requirements, and as he sees and sums up the position prior to his decease, endeavoring to provide for his dependants or allow them to become possessed of such part of his estate as he thinks proper, just and fit. The estate may consist of real and personal property which could not be easily divided without first realising on whatever is comprised, were he not to make a will and allow division according to law. After possibly years of hard work and saving a person naturally wishes to insure that such property as he has acquired will be distributed in a proper manner, and to such as are considered justly entitled to share in the estate on decease, or, the desire may be that dependants will be provided as amply as circumstances will allow. Then, too, he may wish to guard against someone receiving an advantage to which they have little claim, other than by relationship, or who may already have obtained benefit and be amply provided for.

Who may make a Will?—Any person whether married or single, who has attained the age of 21 years, and who possesses anything of value, is competent to make a will. As it is most essential that a will be properly drafted and executed, to avoid any possibility of doubt or wrong interpretation, it should be in simple language and direct in instruction. Every person possessed of means, even if not of great amount, should make a will and lodge it away from his home for safe-keeping. Banks are the usual depository of these documents and care for them without charge to their customers. Having decided to execute this document it is wise to give the matter full consideration and definitely decide on the form it is to take, that is, outline a plan for the investment or distribution of the estate should death occur. It is wise to reach certainty in this regard as otherwise you may be unintentionally influenced by the party preparing the document, and who is not fully conversant with the full facts or intentions. No two persons' estates are alike and you cannot set down any hard and fast rule as to distribution and it follows that the testator should be the person giving the directions, the person preparing the will, setting these on paper with proper regard to any omission of which the testator may not be aware. If your estate consists of assets which could easily be converted into cash it would be an easy matter, but where the ownership is of land, leases, stock and plant, shares, and so on, it naturally follows that considerable thought must be given to obtain fair and even distribution. Another matter that should receive due thought is the appointment of executors. Only one is essential, although two are wise, as one may predecease the testator. The executor, or executors, should be a person, or persons, in whom the testator has full confidence and who are competent and willing to act should the need arise. The main things to remember then before the preparation of the will is to know what you intend it to contain and that you have executors in whom you have confidence and who are willing to act. Now after the will has been prepared and is ready for signature assure yourself that it is in keeping with your requirements. For such reason it is advisable, if in the slightest way complicated, to take it to your home and then quietly study its contents at leisure. If you are satisfied with it do not delay its completion and proper lodgement in a safe

and known place for keeping. If it requires alteration it is advisable to have a new document prepared but again do not delay as after all it is your intention to make your will and not just play with the idea.

Some of the requirements for a valid Will.—A will must be signed at the foot or end by the testator. Such signature to be made or acknowledged by the testator in the presence of two or more witnesses, who are all present at the same time, and who must sign as witnesses in the presence of the testator and each other. Any words that follow the signature of the testator will have no effect. If the will consists of several pages it is only absolutely necessary that the signature should be written at the end of the writing on the last page, though it is usual and advisable to sign at the end of every page for greater security. If the testator cannot write, he may make his mark, but this must be done in the presence of two witnesses who must both be present at the same time. Any person may be a witness provided he or she is intelligent enough to understand the act. It is not necessary that the witnesses should see or be informed as to the contents of the will, though if corrections are made it is advisable that the witnesses should see these, to be able to verify to their existence if necessary. It is also usual and desirable, though not absolutely essential for the testator and witnesses to initial any corrections or interlineations or erasures. Any such alterations made after the will has been executed have no effect, unless they are made under the same conditions as an original will. An executor may also be a witness, but he cannot also be a beneficiary, as no person under a will, or the wife or husband of such person, should be a witness, for although in that case the will is not invalid, yet such persons' interest under the will lapses. It might be interesting here to cite a case which brings out this point, and which was decided in court after considerable argument. A lady made a will in the proper manner, but seven years later made another will containing the usual clause revoking a former wills. The latter will was attested and witnessed by two witnesses, one of whom however was the husband of the main legatee. Both wills were admitted for probate, and the question arose as to what was their combined meaning and effect. After argument and consideration the Judge gave his decision that as the later will was witnessed by a person whose wife was practically the sole legatee or beneficiary this nullified the later will and the earlier document would be accepted. This then resulted in a distribution of the estate which was not the last wish of the testator. The verdict and result is rather confusing, but the case may be taken as a warning that where a later will is meant to revoke an earlier one, it should plainly say so. Practically without exception the last will in date is the one meant to be effective.

tive. The trouble is, of course, that many old people quite forget the wills they have made or when, and so cause confusion, often leading to litigation and expense amongst their surviving relatives. It should always be remembered that no one who takes a benefit under a will should be an attesting witness to its execution, for, though the will may stand good, the benefit is lost. And this rule applies equally to the husband or wife of such a witness, and so may defeat the intention of the testator, and must be avoided. Should a further case come before the court for decision the Judge is bound to follow the earlier opinions by reason of their not being further contested at a higher court.

The Form of a Will.—No particular form is required although most stationers supply a will form for about sixpence. This is fairly generally used, but mainly by the novice, so here again let us stress the need for preparation by a competent person. Any omission usually leads to expense even though it leaves the context of the will as before. In preparation no unnecessary words should be used, but the testator should express his wishes simply, clearly, and without ambiguity or doubt. The object of the testator should be clearly given and the gifts likewise described. If all the property is to be left in one lump it is better to say so rather than attempt to enumerate it. He should always take care to dispose of the whole of the property. An executor, or executors, should be appointed. The date of execution is usually placed at the end of the will. After the testator's signature it is usual to insert the attestation clause. This generally reads:—"Signed by the said testator as and for his last will and testament in the presence of us both present at the same time who in his presence and in the presence of each other have hereunto subscribed our names as witnesses." The witnesses sign beneath this clause. The insertion of this clause facilitates proof. If it is absent affidavits by witnesses must be produced, proving that all the formal requirements of execution have been complied with.

The Revocation or Annulment of a Will.—This is done by:—(1) The marriage of the testator subsequent to execution. (2) The execution of a later will or codicil inconsistent with the former. (3) By any writing executed in the same way as a will and declaring an intention of revoking a will. (4) By burning, tearing, or otherwise destroying the same with an intention of revoking it. As regards the latter. It is definite that there must be a destruction. Merely cancelling the signature will not work a revocation. The revocation of one will does not revive an earlier will. Destruction by burning is the only safe and sure way of guarding against the restoration of an older will and an endeavor to ultimately prove it for probate. A previous beneficiary may become aware that he or she has been excluded from a later executed document, and at some opportune time gain access to the last will and conveniently destroy it. The former, and existent will would then operate, although court action might follow in the endeavor to prove the execution of the later document. It would be difficult to prove the later wishes of the testator, and even if a decision were given to annul the existing will and allow the testator to have died intestate, that is dying without a valid will, the object of the later will would again be defeated and division made in accordance with the law.

A Codicil to a Will.—This must be executed in the same manner as a will as regards dating, execution, and attestation of witnesses. It is employed when the testator desires to make alterations in his will already executed, and such alteration is not of great difference and easily understandable. The added writing follows the previously written and completed document. If the testator desires to recast his will it is better to make an entirely new will, at the same time revoking the former will and seeing to its permanent destruction.

Grounds upon which a Will may be attacked and possibly become worthless.—Mainly these are:—(1) That the will has been revoked. (2) That it was not duly executed. (3) That at the time of its execution the testator was not of sound mind, memory, or understanding. (4) That its execution was obtained by undue influence or fraud. (5) That the testator did not know and approve of the contents of the will. There is one point to be particularly stressed, and that is the disadvantage of an estate continuing for a long period after death of the testator. This is usually created by the widow receiving a life interest in the estate, and on her death division in accordance with instructions. Recent years have especially proved the fallacy of this. It was expected the widow would be comfortably provided for by income from the property. This was usually worked by beneficiaries, and gave the widow no power to realise on any assets if necessary. Owing to adverse seasons the income became insufficient to meet the essential expenses to carry on, and she, in advanced years, had the worry of trying to keep matters going, and usually became involved and in straitened circumstances. Actually she was expected to have comfort and freedom from worry in old age, but the opposite resulted. Special care to avoid such a result is strongly advocated when framing a will. The foregoing emphasises the need for

every wise person possessing means to make a good and proper will, and after execution in the lawful way, lodging it in a well-known place, away from home, for safe custody. If alteration is necessary, do not hesitate to make a new will and properly destroy the old." (Secretary, B. Phillips.)

MURRAYTOWN.

June 10th.—Attendance, 8.

QUESTION BOX.—Discussing the question: "What is a profitable wheat growing price?" the Honorary Secretary (Mr. E. Pitman) said there were many things to be considered, one of the first being the price paid for the farm, i.e., the amount of interest that had to be paid each year; how far the farm was away from the port or railway station; the condition of the roads thereto; whether the farm was hilly or undulating, stoney or cut about with creeks, &c. He considered he could average some profit at approximately 10s. a bag at the port. Mr. Joppich said that hilly country was more costly to work than level land owing to the shorter life of the machinery and the amount of strength required for working. He thought that on 18bush. average land wheat growing would pay at from 3s. 4d. to 3s. 8d. a bushel—much depended on the farm management. Mr. Borgas said that if the interest bill was not too high he thought there should be a profit in growing wheat in average years at, say, 10s. per bag. Mr. Joppich asked how to treat sitting hens that were infested with lice; the hens invariably left the nest before the chicks were due. Both Mr. Ryan and Mr. Jackson advised the use of insectibane for the nest and also on the heads of the young chicks at two weeks' interval. Mr. Borgas initiated a discussion on harrowing wheat after it was up, and Mr. Ryan preferred to harrow red soils in a dry year immediately after a rain. Mr. N. Scholz would only use sharp harrows if harrowing a growing crop. Mr. Joppich said much depended on the state of the soil. If loose black soil one would probably pull a lot of wheat out of the ground.

UPPER WAKEFIELD.

July 6th.—Attendance, 19.

WHITE HEADS IN WHEAT.—The following paper was contributed by Mr. R. Herriott, B.Sc. (Agric.):—

"Every year at harvest time one hears farmers discussing the prevalence of "white heads," which have appeared in their crops. There is absolutely no doubt that the loss from this cause in the Australian wheat belt is very considerable each year. One occasionally hears or sees cases in which losses are estimated at above 50 per cent. The so-called "white head" becomes particularly noticeable in wheat crops because of its characteristic premature ripening, together with its bleached and whitened appearance. It usually possesses no grain, although occasionally heads will be found that contain a few grains of a very inferior sample. The causes of their appearance are many, but they can be divided into two distinct groups, those due to some meteorological accident, i.e., some weather upset, and those caused by the secondary effects of harmful fungi, withdrawing nourishment from the roots of infected plants.

Meteorological Accidents.—These include such conditions as frosts, hot winds, droughts, or dry spells and excessive moisture. Late frosts leave their mark upon wheat crops in some locality every year. The chief cause for damage is that the young emerging ear cannot stand the chilling to which it is subjected on frosty nights. The reproductive organs present within the glumes are therefore rendered inactive, and although the head may continue to develop normally, no grain is set. Affected plants may be picked out in the wheat crops before the actual appearance of "white head" by their characteristically lighter green color. Frost at this stage may also cause a weakening of the basal nodes of the straw leading up to lodging after some light rain or wind. Hot winds also have a detrimental effect upon the developing ear, in that

they cause a very rapid increase in the normal transpiration rate, with the result that the roots, especially if the crop be sown on stubble, have difficulty in making up this moisture deficiency. The plant cells at the top of the ear then become desiccated, and die. With the low average altitude of the Australian wheat belt, open character of the country, and relative absence of shelter, wheat crops must inevitably suffer from hot winds, and yields may be regularly reduced from 20 up to 50 per cent.

The effects of hot winds and frosts are often unnecessarily confused. Frost mainly takes its toll in low-lying areas, and as all flowers in the ear do not mature at the same time, any part of the ear may be affected. Sometimes it will be the tip, sometimes the flowers in the centre of the ear that are affected. Hot winds, on the other hand, are invariably more noticeable in open plains or undulating country, especially along the tops of ridges. In this case we have either all the flowers in the heads killed or those from the top downwards, resulting in the characteristic "tipping" of the wheat crop. A knowledge of local climatic conditions should also help greatly in separating these two causes. Deficient moisture supply is closely linked up with the effect of hot winds, and the symptoms seen in the wheat crop are inseparable.

Attention to the following points should assist greatly to reduce losses from these causes when they occur regularly in any particular district:—

1. Sow early maturing varieties, as these will ripen earlier, and possibly miss the troubles referred to, especially hot winds.
2. Sow at times recommended in your own particular district.
3. The application of superphosphate increases the rate of ripening, and hence reduces loss from these causes.
4. The adoption of early and clean fallowing greatly increases moisture conservation.
5. Wheat sown upon a well consolidated seedbed invariably roots better, and is consequently more able to supply extra moisture needed during the occurrence of a hot wind.

Coupled with the effects of frost, wind, drought, &c., we also have those injuries caused by excessive moisture. During the early stages excessive moisture is evident, particularly from the fact that the crop "yellows off." This is due to the combined effect of lack of nitrate nitrogen in the soil, it having been leached out in drainage waters, and the coldness of the soil, consequent upon its high moisture content. The development of "white heads" from this cause is chiefly due to the fact that such conditions greatly favor diseases like take-all, foot rot, root rot, &c.

Botanists definitely regard fungi as plants, and, like plants, they develop whenever climatic conditions are favorable from spores. They are also parasitic in nature, and can therefore only develop where host plants are present. When spore and host plants are present, therefore, climatic conditions will determine the severity of the attack. Muggy conditions are considered as favorable for the maximum development of most fungi. Once growing upon the host plant, they become dependent upon it for nourishment, and it is this withdrawing of nutrients from the host plant, thus reducing its vigor, which accounts for the harmful effects of these parasitic fungi.

TAKE-ALL.

Take-all has been known to exist in Australia for over 60 years, but recently the disease has been shown to be caused by at least three different parasites, each developing its own characteristic symptoms. The three diseases are now commonly known as take-all, root rot, and foot rot. Much confusion exists between diseases due to these parasitic organisms and those due to wind and frost. In the latter case the straw usually retains a clean appearance, whereas in the case of the fungus diseases definite brown or black discolorations of the basal nodes of the stems are always present. Parasitic diseases normally occur in over-wet seasons, especially in unconsolidated areas, whereas hot winds prove more disastrous in drier seasons. Both troubles, however, can quite possibly occur in the same crop at the same time.

Take-all may be distinguished from the other root diseases from the following description:—It invariably appears in more or less rounded patches or strips of varying size. In worst cases the plant dies back before the stalks appear. In less severely affected plants a stalk may appear, but it soon becomes stunted, and rarely matures an ear. If ears be formed grain fails to develop, and what are known as "white heads" may be seen through the crop. The roots have a characteristic appearance. They become stunted and deformed at an early stage, and may be quite thickened and knotted close to the stem. They are always excessively covered with root hairs, accounting for their characteristic woolly appearance. The stem bases show a distinct black coloration, extending above ground level, and covering the length of the stem for about 2 in. The discoloration is partly superficial, and can be scraped off. In later stages this dark mass becomes distinctly dotted with small black bodies, which contain the seeds or spores of the fungus. On moistening, these fruit cases burst, liberating their seeds, which germinate and grow on wheat, rye, barley, barley grass, &c. In the

absence of any suitable host they soon die. It has become shown, by experiment, that when the soil temperature is above 80° Fahr. it is impossible to even give wheat take-all, whereas at very low temperatures high infections are recorded. Our winter temperatures are very close to those for maximum infection, thus making control measures much more difficult. So far as is known, all our wheat varieties are equally susceptible to the disease, and take-all may be found on all types of soil, but is most prevalent in moist, moderately warm springs, on land sown with wheat year after year.

ROOT ROT.

Root pest is a very similar disease, affecting the heads in exactly the same way as take-all. It does, in fact, quite often occur together on the same plant with it. Certain differences do occur, and these are pointed out in the following few lines:—Take-all develops in more or less circular patches, but with root rot no such regularity occurs. In the more typical cases affected plants are scattered through the crop, and this invariably happens even when some affected plants occur in patches. It usually goes unnoticed until "white heads" make their appearance, and if any grain is formed it is always shrivelled. The stem discoloration is less marked than with take-all, and varies from dark brown to black in color. It is partially superficial, and can quite easily be mistaken for take-all. The discoloration is, however, usually in spots or streaks rather than generally distributed, as was the case with the latter. This disease is probably as equally common as take-all, and occurs under very similar conditions. So far, root rot has only been discovered on wheat and barley grass; hence, as with take-all, cleaning the land of barley grass is an important factor in its control.

FOOT ROT.

The third disease of this group, foot rot, resembles root rot in general characteristics much more closely than take-all. It may be identified by the presence of one or more dark brown streaks or spots at the bases of the affected stalks. Unlike take-all and root rot, however, this dark discoloration is not superficial, i.e., cannot be scraped off, does not usually extend above ground level, and is usually accompanied by a greyish discoloration along the stem. Brittleness of straw with the tendency to snap off at ground level is also a characteristic.

The disease is not particularly common in our wheat belts at present, but it has a particularly wide range of host plants, it having been found upon wheat, barley, rye, and many grasses, including barley grass.

Reviewing these three diseases, then, it will be seen that they are alike in all the main essentials. Their ultimate effect upon the wheat crop is the same; their host plants are, in most cases alike, and the predisposing factors, such as excessive dampness, lack of consolidation of the seedbed, &c., are found to operate with equal importance to each disease. It is little wonder, then, that this group has in the past been regarded as take-all only, and because of this similarity conditions tending to control one will be found to control all three. In connection with the control of this disease, it is unfortunate that infection comes through the soil and not through the seed, as the case with, say, stinking smut, thus removing any possibility of controlling it by pickling the seed. It has also been pointed out that all varieties alike are affected, which eliminates any chance of control by seeding immune or resistant varieties, as can be done with most other diseases. Starvation of the causal organisms, combined with the exercising of great care not to bring about infection in hitherto unaffected areas, are the only possible means of controlling the disease.

METHODS OF CONTROL.

No one cultural operation can account for its control, and success in this direction definitely depends upon the intelligent employment of each of the following interdependent practices:—Although the theory of agriculture generally deplores stubble burning, the securing of a good, clean stubble-burn in badly affected paddocks does much towards the control of this disease. Where only small patches of the disease occur, and these are surrounded by a normal vigorous straw growth, little difficulty will be experienced in securing a good burn; but where more serious infections occur it will quite often be necessary to use harrows, &c., to drag straw over these patches before a successful burning can be ensured. The object of burning is to destroy as much as possible of diseased roots and straw. If not burned, the infected parts of the stubble may be blown about the paddock and into other paddocks, especially if broken up by the trampling of sheep and horses.

Paddocks which have been allowed to go to pasture should preferably be burnt, where possible, before fallowing, as the growth of barley grass, spear grass, silver grass, &c., greatly favors the spread of these root-rotting diseases.

The importance of early fallow in connection with disease control cannot be over-emphasised. The ploughing-in of infected stem bases and roots will cause the spores to germinate when moisture conditions become suitable. Having germinated, these spores must find some susceptible plant to attack, or else die of starvation, which leads up

to the fact that clean fallowing is an essential control measure. Self-sown wheat, barley, and barley grass are all attacked by these diseases. Consequently, the existence of such plants on the fallow only turn it into a breeding and multiplying ground for the various fungi, with the result that they will be even more prevalent in the succeeding crop.

The working of stubble land dry is also a measure to be avoided wherever possible, for under such conditions infected stubble is very brittle, is broken up into numerous small pieces, which are then blown about by wind, and cause a rapid increase in the size of infected patches, and possibly extending the disease into hitherto clean areas.

Certain crops, notably oats and peas, are not affected by these "root-rotting" fungi, and the introduction of these into the farm rotation proves a valuable step towards the control of these diseases. After the growing of such a crop it is essential to fallow early and cleanly before again sowing wheat.

The practice of sowing dry also greatly increases the spread, as both fungus spores and wheat seeds will germinate together with autumn rains. If the variety selected is sown as late as possible after autumn rains it is highly probable that many take-all spores will have germinated and died before the wheat gets away, with the result that take-all infections will be minimised. The application of fairly heavy dressings of superphosphate does much to control the disease. This is probably due to the fact that earlier maturing and more vigorous plants result, and these are better able to resist the attacks of fungi. Waterlogging is also a predisposing factor, for wherever water tends to lie on the surface for any length of time the effects of these three fungi are always very much more severe than on well-drained land. These root diseases will be found to be worse on sandy land in one season and clay land in another. The lighter soils are usually the worst affected, and this is definitely due to the fact that difficulty is experienced in obtaining a good firm consolidated seedbed about 1½ in. x 2 in. deep. The thorough preparation of the seedbed, so that there is at seeding time a very firm seedbed at a depth of about 1½ in. is one of the most important factors in ensuring a good, even germination, and the development of strongly rooting, abundantly vigorous disease-resistance plants. If wheat is planted deeper than 1½ in. considerable time and energy is wasted by young seedlings in developing their permanent rooting system at the 1½ in. level. The permanent root system is then forced to develop in a very poorly compacted over-aerated region of the soil, and the resistance to take-all and its allied diseases is very greatly lowered. The feeding off of crops on affected land must never be practised, as the corresponding reduction in vigor of individual plants will greatly increase their susceptibility to the take-all group of fungi. If cutting infected crops for hay, cutting high so that diseased portions will not be spread over the farm is a highly desirable practice. For reasons already stated, infected paddocks should never be allowed to go to pasture. An oat crop or good clean fallow is the only preventive we know. The dumping of bags in bare patches in paddocks caused by these diseases cannot be too strongly deplored. A moment's reflection should show that such practices only tend to distribute spores from paddock to paddock or farm to farm.

If all the above recommendations are conscientiously carried out—and many of them are simply practices which should be carried out in ordinary farm routine, quite apart from all considerations of disease—take-all, foot rot, and root rot will be greatly reduced, if not entirely eliminated from our wheat fields." (Secretary, C. Neumann, Halbury.)

YORKE PENINSULA DISTRICT.**KILKERRAN.**

July 11th.—Attendance, 13.

PREPARATIONS FOR SEEDING.—Mr. C. Hill read the following paper:—"In making preparations for seeding, the work actually begins at harvest time, when the practical farmer selects the varieties of wheat he requires. The selection of good seed is most important, and too much care cannot be taken to see that it is true to type and free from barley, which is very prevalent amongst wheats at the present time. In the selection of seed the farmer is greatly assisted by the crop competitions that are held annually, for after being judged a list of the different types recommended by the judges as being fit for seed are advertised. The value of the experimental farms cannot be over-estimated in proving the most suitable varieties of wheat to grow in the various districts. The correct time for sowing the different varieties must also claim attention. When the object is the production of grain, the late wheats should be sown first, followed by the mid-season varieties, and the early maturing wheats last of all. The grader is the best machine to use for cleaning the seed; it removes cracked and pinched grains, and turns out a sample that is almost perfect, which gives better germination and a stronger plant. Pickling must also be carried out thoroughly. If dry pickle is used, care must be taken to see that the seed is dusted as evenly as possible. If formalin or bluestone is preferred, the main point is to see that the grain is thoroughly saturated. It is not advisable to leave the delivery of the super too late for wet weather may cause unnecessary delay. During slack time thoroughly overhaul the drill or combine, and replace any worn parts. A good plan is to blacklead the stars, which will prevent the super sticking so badly. Go over swings, chains, and harness. When horses have been grazing in the paddock give them at least one feed a day for a few days before they commence hard work. Prior to the commencement of seeding fill up the chaffhouse, or, if a power farmer, see that the tractor is in good order, to ensure an uninterrupted run through the seeding operations. The stubble on which the barley crop is to be grown should be burnt off, and for working the ground the combine proves very satisfactory in this district, seed being sown at the rate of 1bush. with $\frac{1}{2}$ cwt. of super. The amount of wheat to be sown should vary a little. For a non-stooling variety I prefer 75lbs. to the acre, and a wheat that will stool, a little less. A dressing of at least 1cwt. of super to the acre is advisable. Seed should be sown about 1in. deep with a light set of harrows behind the combine to level the ground and cover any exposed grains."

TRAINING A SHEEP DOG.—Mr. J. Dutschke read the following paper:—"A dog should be taken in hand at about 4 or 5 months old, or earlier if he shows signs of beginning to work. He should first be put through the elementary course of instruction. Do not try and teach him everything at once, but take him steady, and have patience. Patience is one of the greatest factors in training. Teach him a little every day, and the task will not become so burdensome. When training begins, the first thing that should be taught is obedience. If this is taught right from the outset half the battle will be won. Teach him that by beginning with small lessons, such as to sit up or shake hands. Be very firm in teaching him. When the dog has been told to do something do not rest satisfied until he has done it. Study the dog. If he will not obey, give him a good beating. If that has a tendency to make him nervous or frightened, resort to some other method. Try and gain the dog's confidence. The best way to train a dog that has a tendency to run away is to get him on a chain. Much can be accomplished if a stick or strap is kept handy. Never let a dog bite the sheep when he is driving them. If he does this the best way to prevent it is to muzzle him. A very important thing to teach a dog is to sit down. No matter where the dog is, when he is told to sit down he must do it immediately." (Secretary, G. Heinrich, Maitland.)

FARM CONVENIENCES.

[Paper read by Mr. D. Wright at the July meeting of the Boor's Plains Branch.]

THE HOME.

Our first thoughts should be for conveniences in the home; there are many comforts that lie within the reach of all, that may be added to the home, that will make the work of the housewife more attractive and less fatiguing. One of the most important of these is a water service to the kitchen. This convenience can be accomplished at a reasonable cost, and will compensate the outlay in more ways than one. A good bathroom is more essential in the farm house than many other so-called conveniences. In the matter of lighting there are various plants and lights that are at the disposal of the farmer; in these days the subject of cost plays a large part. The convenience of a good lighting plant is fully realised by those who have the advantage of owning one. Among other conveniences on the farm are petrol irons, butter churns, and washing machines; these can all be added at various times to the home at reasonable

prices, thereby adding comfort to the lot of the farmer's wife. Perhaps one of the most useful conveniences on the farm is the telephone. During busy periods—seeding and harvest—the cost of this instrument will cover itself in time and petrol saved; again, in the case of sickness or accident the usefulness of this instrument is demonstrated.

THE FARM.

It is hardly necessary to stress the importance of having the water laid on to the various sections of work. Water handy to the chaffcutter, stables, cowyards, and pigsties is invaluable, not only for the sake of saving labor and time, but in times of fire. When sidelines are playing an important part in the farming community conveniences and labor-saving devices are being given a prominent part. In altering or building fowlhouses it is a simple matter to build the nests in the front of the house with a trapdoor to collect the eggs. A concrete or cement floor under the roots will facilitate cleaning. Automatic water buckets ensure a fresh supply of water for the fowls and save water carrying. Since the slump in grain prices much attention has been given to the breeding of pigs, and to endeavor to make it pay it is necessary to use every labor-saving device that we can. Self-feeders can be made from old petrol and bitumen drums and 200gall. square tanks. These can be made in various ways and at a reasonable cost. The average gate in the pigyard is one that gives a considerable amount of trouble. An effective and lasting gate can be made from an old square 200gall. tank by cutting the sides and bottom out to the required size and boring a hole through the iron into the post to take a $\frac{1}{2}$ in. bolt. A ramp is necessary where pigs are reared to any extent; a simple ramp can be made out of timber found on the farm, old wooden waterpipes make excellent sides for this. It is a good plan to have the ramp movable, so that in the event of one vehicle being higher than another it can be raised or lowered as required. The cost of running a car as well as a truck has induced many farmers to do away with small trucks, replacing them with trailers behind the car. The cost of building and running a trailer is small against that of the maintenance of a truck. The chassis, springs, &c., necessary for a trailer can be obtained at bedrock prices; the convenience of these vehicles will more than cover the initial outlay. A farmer who is working a small holding will find a one-man bag loader a valuable asset in saving time and work. These can be bought or made from disused waterpipes, bent and rivetted into position. Among the many conveniences to be found on the farm none plays so important a part as that of a well-equipped blacksmith's shop. Forge, anvil, and vice all play their part in reducing costs, and save the expense and inconvenience of travelling to the town to have minor repairs done.

GATES AND MOTOR RAMPS.

Farmgates are not always as convenient as they might be; an excellent idea for all the main gates is to have them made of iron. These make strong gates and add appearance to the homestead. Old water pipes cut and flattened each end and rivetted to angle iron from obsolete machinery will prove to be satisfactory and serviceable gates. Wooden gates can be made easily on the farm, but it is not advisable to use these if they are intended to hold back horses and stock. The iron gate, although it may cost a little more, will have a longer period of service. The ordinary wire gate is generally a source of trouble, and one cannot do better than to refer to the reference to wire gates in the May issue of the *Journal of Agriculture*. A recent addition to farm conveniences is the car ramp. These are to be seen in various shapes and forms. Three types of ramps can be made on the farm that will cater for the majority of motor traffic met with. The first can be made by using two sections out of an old spring-toothed cultivator; the gaps in the sections can be filled with pieces of scrap iron the required thickness bolted or rivetted to the sections. A hole 2ft. wide, 18in. deep, and about 10ft. long is necessary to stop cattle from crossing the sections placed across this pit. This will make an ideal ramp for the average light car. The second type can also be made from material found on most farms. Twelve lengths of 2in. or 3in. piping 2ft. 6in. long are required, also four pieces of T iron or railway iron 3ft. or 4ft. long; these can be found in the framework of old harvesters. The piping when bolted to the T iron and placed over the pit will prove an effective ramp, and one that is capable of carrying the weight of a fair load. The third type is one that will prove to be more costly, because the material is not found on the average farm. However, by purchasing obsolete railway irons and bolting them to two iron supports an excellent ramp can be built. Care should be taken in not placing the irons too far apart, thereby making a trap for stock in which to break their legs. Of the three types I favor the second, in which the centre of the pit is uncovered. This generally proves an obstacle to any stock that may attempt to cross it. The farmer of to-day has proved himself efficient by getting out of the rut of past years by adopting up-to-date and convenient methods, and it is to his advantage to use every convenience and labor-saving device that he can command.

WESTERN DISTRICT.

ELBOW HILL (Average annual rainfall, 11in. to 12in.).

June 6th.—Attendance, 11.

SHEEP ON THE FARM.—Mr. J. Wildman read the following paper:—"For this locality the Merino serves the dual purpose of fat lambs and also wool. This breed of sheep does not produce an ideal carcass for the freezers, but when the season is favorable a very fair lamb can be produced, and by keeping to the Merino the standard of the wool does not receive a setback. The type of Merino should be plain body, clean face, and no wrinkles on body or breach, and carrying a fleece of medium fine wool about 60's count. By keeping the sheep free from wrinkles the flock has a much better constitution, with less trouble from flies. One of the most important things is to be able to calculate the carrying capacity of the farm. This is hard to arrive at in some seasons, but be careful not to over-stock as this entails more money invested, less profit per sheep, and a great deal more risk. With over-stocking the sheep are inclined to stray and are much harder on the fences. The lambs should be dropped about June or July to be on the safe side for green feed in this part. A ewe having green feed when the lamb is at foot will produce a much better lamb than the one having to wait a month or two before the green feed comes after dropping the lamb. This district has more late seasons for feed than early ones, so that the later lamb is preferable. Except in cases where only a few sheep are kept—under 100—the lambs can be dropped all the year. All sheep should be crutched about April or early in May. The sheep should be changed frequently from different paddocks, according to the supply of pasture and number of sheep. They should not be allowed to walk for water in summer; this has a tendency to collect dust in the fleece. Shearing should range from the middle of August until the middle of September; no later on account of grass seeds and dust. Before starting shearing, the shed should be in order, to get the shearing done without delay and to have as fast and efficient shearers as possible to get the sheep shorn with the least number of times of yarding as possible; every time the sheep are driven into a dusty yard with full fleece there is a considerable loss in the value of the wool; it is also harder on the sheep and lambs. Either blades or machines can be used with complete satisfaction, provided the operators are competent men. Machines are very rough on the sheep if not understood. The blades do not bruise the sheep to the same extent as machines. For small flocks, the blades are more suitable and economical. If the wool contains sandy or dusty backs, these should be removed and baled separately. Make the bales true to sample; if it be dusty let it all be dusty, and if clean wool take care to have it clean, and so on in every class. Some farmers do not take sufficient care when shearing and baling the wool, yet it is the leading sideline and also shows more profit than any other operation. Farmers have hundreds of pounds worth of machinery for wheat growing, some hardly ever used, yet too often no provision is made for handling one of the most profitable sidelines on the farm." A good discussion followed.

DISADVANTAGES OF A HOME CONSUMPTION PRICE FOR WHEAT.—The Rev. H. White read the following paper at the meeting of the Branch held on July 11th. The speaker stated that his paper was written in reply to a paper by Mr. Payne, of the Miltalie Branch, which was published in the September issue of the *Journal*:—"Farmers must demand at least the cost of production in order to survive," says Mr. Payne, and adds further, "You must demand it; it is your right." "A guarantee of 5s. a bushel would be the very worst thing that could happen in the interests of progressive farming. The old policy of each man for himself would further entrench vested interests, that have existed too long at the cost of primary producers. The high prices resulted in a land boom that is very largely the cause of Australian difficulties, and to base the cost of production on such fictitious land values is not good business. Furthermore, farmers are told to demand a certain price, but who is to pay this price? Ninety-two per cent.

of our wheat harvest is sold under competition in the world's markets and only 8 per cent. remains at home for food and seed, so that it will be realised that we are not in a favorable position to obtain all that we demand. While this does not prejudice any claim for a reasonable price, it makes it extremely difficult to see how the claim is to be met. Mr. Payne made the following quotation from Sir Otto Niemeyer's report, "So long as the sheltered trades of Australia insist on taking so large a share of the national dividend (and even an increasingly large proportion as the national dividend drops) the difficulties of the unsheltered export trade can only increase." Sir Otto, in the rest of the quotation, shows how difficult the lot of the primary producer is, and points out clearly that the situation can only be met by a considerable reduction in the cost of production. Mr. Payne, who used the quotation advocates the acceptance of the wrong method of adjustment as against the correct one supported by the report. In effect he asks for a protective duty on home consumed wheat. It should be pointed out that there is no proper analogy between the prices fixed by millers and bakers and this suggested fixation of wheat prices. There is no surplus problem if the price of each article is based on the fluctuating price of grain, and so long as neither baker nor miller presumes unduly on the minimum prices, it is wiser to have some basis upon which work is done. To support the dried fruit and sugar industries, a call is made on the living of every individual to support a minority at a much higher standard of living generally than they themselves enjoy. Mr. Payne admits that the price of bread will increase. He speaks of the price-controlling factors in milling and baking, but he seems optimistic when he says that "while you practically double the price of wheat, bread will not increase to any appreciable extent." Based on Mr. Payne's figures—which he will not dispute—flour under this scheme will increase to about £14 per ton, and on the same basis of calculation bread must advance to at least 5d. per loaf, and more in the country. Based on Mr. Payne's calculation again, this increase on bread alone will tax a man and wife without family 13s. a year, the average family of man, wife, and three children 30s. a year, and so on in proportion to the size of family. Calculating the number of people drawing rations as at 20,000, it would cost the Government another £250 a week to provide bread only for these. Nor will the increases stop at bread, it will extend to many other commodities, nearly all of which are used by the poorer classes. Proceeding, it is not a good argument in favor of Mr. Payne's suggestions to quote the duties placed on imported wheat by continental countries. The reason for this lies in a precisely similar scheme (only much wider in its scope) advocated by America to control the price of wheat for its primary producers. This has created a surplus, and the attempts at price fixing and Government control have only increased the problem and will continue to do so so long as the Government is regarded as a paternal pocket into which everyone may dip as need arises. Farmers should know just how small an amount this scheme will really net for them. Based on last year's production, the net increase will be 2d. per bushel, and the average farmer cropping 350 acres and averaging 12 bush. per acre would receive £35, and proportionately more or less according to the acreage and productivity. Mr. Payne admits that his scheme will not save the situation. It may be likened to giving every unemployed man 6d. or so to buy food. This is not solving the unemployment problem. It is like putting a stay against a bulging wall that in time requires more stays to prevent collapse. The whole policy of recent years is a futile effort to bolster up a situation that is wrong—every industry seeking protection, tariffs, bonuses, bounties, &c., until the economic war has proved as disastrous as that waged between nations. Mr. Payne says: "If this were a free trade country it would be fair enough to accept world conditions." If that is so, then the solution of the problem lies along the line of reconstruction, a reconstruction that aims first of all at a good foundation. The shortage in wheat income must be met by concentration in other sides of production, for instance, lambs, wool, poultry, cattle, dairy produce, and bacon, with added keenness to the standards of production in every one of these side lines. I know Mr. Payne will agree with me on this demand for increased quality. Our investments have been largely in the form of land which has depreciated by approximately 200 per cent. Primary industry is setting this chimera of wealth on one side of its ledger and bewailing the fact that its income will not meet expenditure. What must be done? First, let us know the worst, and strike upward from that point. We must base our production costs on the present values, which have a close connection with parity. It is all very well to talk of Australian values. They are represented by the Australian note and are not what they seem. There must be a writing down of values. There must be a revision of tariffs. This seems to me to be one of the keys to the situation, and must be faced boldly and quickly to ensure security for the future. The aim in all efforts to improve methods of manufacture and production is to reduce costs. A comparison of prices will show that where industry is unhampered by Government restrictions or given Government assistance, the cheapening of costs results, and is to the benefit of the consumer. It is reasonable to expect that with the wonderfully improved methods of farming and efficient machinery, the consumer may not look for a cheapening of the finished article,

rather than buying wheat at a price quite in advance of that obtained by farmers who labored under the disabilities of a generation ago? This reduction of costs may not result quickly in a small populated country, but it should be kept in view as a necessity under modern conditions." (Secretary, W. Cooper.)

MOUNT HOPE.

July 13th.—Attendance, 9.

VERMIN DESTRUCTION.—Mr. L. Myers read the following paper:—"In the last few years vermin have increased to such an extent as to become a very serious menace to all farmers, and rabbits are the most troublesome. It is almost impossible to check them entirely, and to keep them in reasonable control takes much labor. The most effective method is with dogs and traps. When starting on a paddock with dogs block as many of the burrows in the morning as can be attended to in the afternoon. Some system must be adopted, such as driving them into a corner, or where they can be caught. If it is possible, make a yard in the corner of the paddock to run them into, or if the scrubby ridges are not too wide, make a V-shaped race with a small yard at the point with a trap, so they can get in and not get out. To do this, use a piece of netting about 3ft. to 4ft. long, and make it into a tunnel with a fairly big entrance, running into a small outlet. Place this right in the corner so that the rabbit has his head in the entrance when he comes to the corner. It is advisable to have water there, but do not allow the dogs to drink too much. If the rabbits are very thick, go over the paddock two or three times in the morning; then follow on with traps, setting one at every open burrow. When this has been done, take the dogs over the paddock again, this time taking a .22 rifle. Many will be easy to shoot, thus saving the dog much needless running." (Secretary, A. L. Myers.)

PYGERY.

July 4th.—Attendance, 9.

FALLOWING.—Discussing this subject, Mr. A. Kammerrmann expressed a preference for early fallowing because grass and weeds were easily destroyed; if left late the grass was too high to be covered. His last year's early fallow was clean, the late dirty. He preferred shallow working. Mr. E. Edmonds said shallow ploughing conserved the moisture better. No matter how often the fallow was worked mustard seeds grew.

He advised, fallow early and shallow, and work it well or keep sheep on it. Mr. Symonds: "See that the plough is in good order and all shares sharp." He kept sheep on the fallow last year; it was hard, but free from weeds. He did not believe in too much working. Mr. Woodrup advised keeping sheep on barley grass in its early stage to prevent too much seeding. Sheep would not eat the seed-heads of barley-grass.

TAILING LAMBS.—Mr. Kammermann said that cleanliness was the first essential. He liked to leave the tail about 2in. long. The very short-tailed sheep were more often blown than those with a longer tail. He did not favor crutching; three years' experience had shown that crutched sheep were badly blown, while the uncrutched were not affected. He cleaned up all that were affected and applied sheep oil. He did not crutch any sheep this year, and out of a large mob he had less than 3 per cent. fly-blown. Mr. Edmonds crutched his sheep because it saved the wool that would only be greasy locks or dags if left until shearing time. Those he missed invariably got blown. When tailing lambs he thoroughly washed the instruments, but did not put anything on the lambs; he had had no losses. He left two joints on the tail. Sheep with the tail wrinkle were the first to get blown. Mr. Woodrup crutched to have sheep clean at shearing time. The crutching wool was clean, but if left until shearing it was lost. He tailed lambs at 3 weeks of age and left two joints on the tail. He tailed the lambs in the sheepyard and kept the tools in a dish of disinfectant water. Mr. Day favored from 2in. to 3in. of tail, the sheep looked better and they kept cleaner than those with a shorter tail. He used formalin in the water for the instruments. A wrinkle-free sheep was rarely fly-struck. Mr. Symonds had so much trouble last year that he crutched his sheep this year and saved half a bale of clean wool. He used sheep-dip at time of crutching.

RABBIT DESTRUCTION.—Mr. Kammermann had found oats and strychnine, or jam and strychnine very good. He dissolved the strychnine in vinegar then mixed with water and soaked the oats in it and distributed them along a furrow made with the poison cart. For burrows he found the ear exhaust was the best. Cynagas was too expensive. Mr. Edmonds thought cynagas was most effective to kill rabbits in the burrows. To deal effectively with rabbits all landholders should destroy simultaneously. (Secretary, A. Day.)

ROBERTS AND VERRAN.

July 5th.—Attendance, 12.

INCREASING PRODUCTION.—Paper read by Mr. E. Pobke:—"Every farmer's aim should be to get the maximum returns in conjunction with an outlay of costs as small as possible. Modern machinery and modern methods are necessary if the occupier of land is to make his business payable. The farmer should study the soil on his holding and work it accordingly. Climatic conditions should be thoroughly looked into, and also the natural herbage growing on paddocks which have been left out for several years. It is beneficial if the farmer keeps an eye and also an open ear on research and experimental work that is carried on in a district with similar conditions to that in which he is situated. He should also be interested in agricultural practices that are published from time to time. Every farmer will place fallow in the affirmative, and fallow is one of the main things for increasing production. Correct rotation of cereals is another vital point. In keeping sheep either for wool or mutton the farmer will find it helpful in keeping his ground in good heart through the sheep's droppings, and they will keep the fallows clean and check the growth of wild bushes which soon appear on grass land. Keep only seed from wheat that has been proved in your district after a 'thorough test.' " (Secretary, C. Masters.)

TARAGORO.

June 8th.—Attendance, 8.

FARM OUTBUILDINGS.—The following paper was read by Mr. E. Benson:—"Farm outbuildings are the most necessitous things on the farm, and without them the farm is not of any great value. All outbuildings should be built strong, weatherproof, and left in such a manner so that any one or more of them may be extended. Most farmers of to-day usually build to carry only what stock they have at the time; such a step is a very grave error. Before erecting, see that the site is on high and dry land; water becomes a menace to all buildings. In building a chaff house, a two-storied building is the better, the top one holding the chaff and the lower the oats. Two or three shoots should lead to the back of the manger of the stable, which should be built directly behind the chaff house, with trap doors. This does away with all hand bagging. A shoot should also be used for the oats. The barn should be erected on a concrete foundation of about 2ft. 6in. high, which ensures dryness, and can quite easily be made mouse-proof. The stable should face the east, with the back closed in, with a door in the centre, the water trough to be in the back yard so that the horse can have a drink when they wish, also a roll. Each horse should have its own stall, with collar, hames,

and winkers hanging in same, and stalls should be cleaned out every day. *The Pig Sty* should be built facing the east, with a fairly well-sloped floor, with a drain at the foot running into a pughole. This enables all water and slush to get away and the sty can be easily kept clean. Fowl houses should be fairly open, with roosts of piping hanging by wire from the roof. Piping should be used; wood provides a harbor for tick. Machinery, sheep, and shearing sheds should be under one roof. *The Men's Living Quarters.*—Some farmers prefer the men to sleep under the same roof as they do, whilst others desire privacy, and wish their men to live away from the house. If the latter, give the men comfortable quarters, as many a good man has left his job against his own and his employer's will on account of uncomfortable living quarters. These should be built of stone or wood and iron, lined with suitable material, and should have an open fireplace and a large window" (Secretary, T. Winters.)

WARRAMBOO.

July 4th.—Attendance, 11.

PREPARATIONS FOR SHEARING.—Mr. H. Tucker read the following paper:—"On most mixed farms there is always a certain amount of preparing to be done before shearing can be commenced, because farmers have to make the most possible use of what sheds they have throughout the year. After the shed has been cleaned out, see that it is clear underneath the grating in the catching pen, and, if not in possession of grating, posts laid down over the ground close together in the pen will be better than nothing at all. There should be shed room to cover at least 100 sheep—say, 40 in the catching pen, and 60 besides. Shorn sheep should be turned out through the shed into a separate pen. These pens are best if made fairly high and blind, for a shorn sheep is very active at times, and it takes more than netting to hold him. Floor space for at least two men is wanted in the shed; shelves nailed up at each place, and also water pots nailed to a post. A 5lb. jam tin makes a good water pot, and there must be something put in the bottom of them, such as a piece of leather cut out to fit in. This is to save the points of shears. Everything necessary for the job should be on hand, such as wool packs, blue string, tar for cuts in sheep, and blowfly oil. Stencils should be used to make the branding of the bales look neat. Neatness in appearance goes a long way with buyers in the wool stores. These can be made out of a kerosene tin with a little care and time. All dirty sheep should be crutched before being allowed to enter on the shearing floor." (Secretary, F. Chilman.)

VARIETIES OF WHEAT FOR THE DISTRICT.

(Paper read by Mr. O. J. MURPHY at the June meeting of the Warramboos Branch.)

The selection of wheats for seed purposes is a matter of prime importance. At the present time the price of wheat is at a low level; and it should be the aim of every farmer to select varieties which are likely to give the highest yields at harvest time; yield is of more importance than area.

Generally speaking, the comparatively low rainfall of this district coupled with the fact that spring conditions in the shape of hot north winds and late frosts are often very severe, call for sowing of early varieties of wheat, and particularly varieties which do not carry much flag. Gluyas is the best known variety of the latter type. However, it is not advisable to limit the selection of seed varieties to one or two early varieties under the prevailing conditions of this district. Seeding operations extend over a lengthy period, from early April until the end of June. In some cases, this period is exceeded. Moreover, we are called upon to deal with a wider range of soil types and conditions, new or virgin ground, stubble ground, grass ground, fallow, sandy ridges,

DEPENDABILITY.

There 'are' few people who cannot recall some instance where a widow, left sole Executrix, has been badly advised and lost all that she had—where the man whom everyone trusted, speculated with the moneys placed in his care and was unable to make restitution—or where the fortunes of a family have been wrecked by the absconding of a trusted friend.

DO NOT TAKE RISKS—APPOINT

ELDER'S Trustee and Executor Company Limited.

AS YOUR EXECUTOR AND TRUSTEE.

and low-lying flats of comparatively firm soil. It is not to be expected that any one variety of wheat sown at any time between April 1st and June 30th on any one of the varieties of soil mentioned will always give good results. The selection of varieties to sow calls for good judgment on the part of the wheatgrower.

The chief varieties of wheat grown in this district at the present time are Gluyas, Late Gluyas, Golden Drop, Canberra, Ford, and Nabawa. Other varieties not so extensively grown are Queen Fan, Quality, Waratah, King's White, and Jacobs'. Several of these varieties failed last season when red rust and take-all were prevalent, but it should be pointed out that the yields obtained and the degree to which the varieties were affected by disease depended very largely on the time of sowing. King's White sown early in the season during April yielded a poor sample, weighing approximately 57½ lbs. to the bushel. The same variety of wheat, sown in the latter part of May, produced a good sample weighing over 63 lbs. per bushel. The 1932 season was abnormal, and consequently wheat varieties should not be judged on that season alone.

The writer recommends the selection of varieties which have a good record over a period of years. It is not a paying proposition for the farmer in comparatively new country to experiment extensively with new varieties, the testing of new varieties is interesting and essential if one wishes to keep pace with the times, but these varieties should be limited to one or two and sown on small areas.

GLUYAS AND KING'S WHITE.

Gluyas has given the best results during the past four seasons—two semi-drought years and two comparatively wet seasons. This variety has been one of the leading wheats in South Australia for several years, and in the writer's opinion is a variety well suited for this district. I recommend it for sowing on fallow, stubble, or grass ground during May and June. Sown in April there is a danger of the variety being affected by frost. The chief objection to this wheat is its liability to lodge. The variety should not be discarded on this account, because even if lodged the toughness of the straw permits clean reaping. Gluyas is primarily a grain yielder. It is not a good hay wheat, and its chaff is hard and not attractive to stock. If cut for hay, the binder should be used when the crop is green. Cut green; the hay will retain its color in the stack. King's White is an early bearded variety, which has been used extensively at Roseworthy College over a number of years for wheat breeding. Many well-known varieties, such as Sultan and Caliph, are closely connected with King's White, which is one of the best hay wheats grown in Australia. During the past four seasons this variety has yielded little less than Gluyas. It has the following advantages over Gluyas:—A considerably better hay wheat, a more valuable stubble for stock feed, and a chaff which is very attractive to stock, notwithstanding the beard. This variety, on account of the protection afforded by the beard, is not affected by frost, and the heads are never tipped by hot winds. Although it matures in a shorter period than Gluyas, it can, if necessary, be sown with more safety in the early part of the season. On the other hand, it is more susceptible to attacks of red rust than Gluyas, and on account of the bulky chaff and the bearded head, the harvesting of this variety by means of the ordinary stripper and winnower is a more irksome job. Present day harvesters and threshers handle the variety quite effectively.

On account of the peculiar formation of the land in this district, viz., sand rises liable to drift, with intervening low-lying flats, the effects of frost are most severe. A quick-growing bearded wheat, such as King's White, is a very suitable variety, well worthy of trial. It should recommend itself, particularly to the owner of a new block where the presence of stumps does not permit the use of a binder. The cocky chaff from King's White is bulky and more attractive to stock than the chaff of any other variety we have grown.

NABAWA.

Nabawa was the leading variety of wheat in South Australia last year. It has been strongly recommended by our Agricultural Instructor. Nabawa is a mid-season variety. It is a good grain wheat, and appears to be immune to flag smut. On this account it is recommended for sowing on stubble ground. Many failures have been experienced in this district with Nabawa, probably due to the fact that its habits of growth are not well known. In this district Nabawa must be sown early and on clean ground if the best results are to be obtained. It is a very slow grower in its early stages, and cannot on that account compete with rubbish, such as barley grass and mustard. This wheat should only be sown on new ground, free from weeds, or on well-worked fallow. It should give good results sown early as a first, second or third crop on new ground, before weeds have made their appearance. It is not to be compared with Gluyas, King's White, Canberra, and other early varieties for late seeding on grass land.

OTHER POPULAR VARIETIES.

Late Gluyas is a popular variety in this district. In our experience it is not so good a yielder as Gluyas. This variety was badly affected by rust last year. It stands up better than Gluyas, is an easier threshing wheat, and carries more flag. It is doubtful

whether this selection from Gluyas will stand dry weather conditions as well as the earlier variety.

Canberra and Ford wheats have lost some of their popularity. Canberra appears to be susceptible to loose smut. It is an early variety, which has given good results sown late in the season. Ford regained some of its former popularity last season on account of its resistance to red rust. Like Nabawa, this variety requires a good clean soil and little competition with weeds in its early stages if it is to give a good yield.

Waratah is an early variety, having the same period of growth as Gluyas, and claiming Gluyas as one of its parents. It is better hay wheat than Gluyas, stands up well, is an easy threshing wheat, and rust resistant. It is New South Wales's most popular variety. The spikelets of the head of this variety may afford some protection against frost.

Of the varieties mentioned, Gluyas, King's White, Nabawa, Waratah, and Late Gluyas are five good wheats for this district, likely to give good results over a period of years, provided always that due consideration be given to the time of sowing and the class of soil on which the varieties are sown.

Of the new varieties which have been prominent within recent years Sword, a Ford crossbred wheat, should be well worth a trial by those interested in the testing of new varieties. Sword has shown a marked resistance to red rust, and has given very high yields in other parts of the State.

CARE OF THE MOTOR CAR.—Paper read by Mr. A. Hein:—"The correct lubrication of the engine is the most vital point to be considered, being careful to see that the grade of oil recommended by the manufacturers is used and that it is kept at the correct level. Cheap oil will generally lose its body in a few hundred miles, cause wear in the main bearings, and run up the repair bill. It is important that compression be equal in all cylinders. Faulty compression may be shown in loss of power or missing in the engine. Compression should be tested occasionally by turning the engine until resistance in each of the cylinders is felt. If the compression is weak in one or all of the cylinders the valves may be pitted and not seating properly, and need regrinding. The piston rings may be weak or poorly fitting. Any of these faults should be corrected immediately. If the valves are allowed to remain coated with carbon for any length of time they become badly pitted, and are much harder to grind to a smooth seat. Inspect the wiring, terminals, and spark plugs, and see that all connections are tight. Examine the battery regularly. See that all the cells are filled to the proper level with pure distilled water. Keep the radiator full of water and see that there is no obstruction in the flow of water through the radiator tubes. Examine the foot and hand brakes, they must work freely and be properly adjusted. The steering should be examined for loose bolts and nuts. Attention to these parts will add to the safety and pleasure of driving your car. Shackle bolts should not be made too tight, or the result will be hard riding and spring breakage. They should be tightened only until end play is removed. Examine the tyres for any cuts or bruises. If they are not taken care of at the start, sand and water will work under the outside tread and loosen the entire tread. Most tyre troubles are due to under inflation. Do not neglect necessary adjustment and repairs. Do not race the engine. Do not start with a jerk, always engage the clutch gradually and the car will start easily. Do not forget above all else that the car is a fine piece of machinery and that one will be repaid many times in excellence of service for the care and attention given it." (Secretary, C. Altmann.)

July 15th.—Attendance, 24.

CARE OF FARM STOCK.—Mr. A. Braendler read the following paper:—"Horses that have been spelled in the paddock for a long time should, on being brought into the stable, be fed on long hay for a day or two or only a small quantity of chaff. Never work them too fast for the first few days. If they have worked for a few weeks and are then to be rested for a few days, do not turn them out on short green grass without giving them dry feed every day or night—sudden changes will upset them. Never change the feed or water suddenly; always water before feeding, never just before hard work. To get the best returns from cows see that they have free access to water and provide a lick of sweet bonemeal mixed with a little salt in a box convenient to the drinking trough, especially in summer. Never change their feed suddenly and always see that they have plenty of it. A change from one paddock to another is beneficial. Do not allow them to graze on fresh green clover early in the morning when the grass is very wet and dewy, because they are likely to bloat. Always try and give them a little green in summer. If this is not available, feed them on lucerne hay, bran, clover hay, sweet green hay, or ensilage. Always feed regularly and keep them in good condition. It has often been stated that sheep only need be taken to water about twice a week, but my experience is if they have the water in their paddock where they can drink whenever they like they will keep in better condition and do on less grass through the summer. When the grass is green and it is desired to fatten them quickly, change them from one paddock to another every two or three weeks. Do not do this early in the morning when the grass is very wet or dewy. When the grass is dry do not shift them into a paddock containing green stinkwort that is just coming out in flower or there will be serious losses. Pigs will do much better if clean water and clean feed is provided for them. A little paddock in which to run and feed is good for all breeding sows, and young growing pigs will thrive if run in a paddock where there is plenty of green soft grass growing, barley, dandelion, or clover. The more milk and grain that can be fed to them the better they will do. Always have charcoal and ashes in a box for them, with plenty of water, especially in summer. Always remember that free access to water applies to all animals, especially in summer. and also do not forget to provide shade in summer and shelter in winter. (Secretary, C. Altmann.)

MURRAY BRIDGE (Average annual rainfall, 13.59in.).

June 28.—Attendance, 14.

PRUNING.—With suitable diagrams and sketches Mr. A. H. Paterson, Agricultural Instructor at the Murray Bridge High School, gave a lecture on "Pruning." He traced the growth of the tree from its seedling stage to the time when it would be in full fruit. Although from the backyard point of view it was not always necessary to bud a tree to get fruit, to run an orchard on commercial lines it was essential to have a standard tree bearing fruit at the right time. The unfixed type would give spasmodic results, causing much inconvenience and waste of time. The budding should be done about 4ins. above ground level. Pruning for the first four or five years should aim at building up the framework of the tree to a wineglass shape. The first pruning would be to cut off the topmost part of the seedling. The strongest growth is at the topmost part of the tree. The second pruning required the selection of three limbs for main arms. When the tree had reached the fruit-bearing stage one of the first principles to remember was to keep the tree in a state of semi-debility—not too vigorous nor too weak. The fruit and leaves should be kept down to the bottom part of the tree as much as possible. Especially was it important where fruit was liable to be sun-scorched. Strong growth at the top and good fruit production did not go together. It was necessary to supply a leader for each arm to draw up sap, not to supply fruit. On a normal tree about half the leader should be kept and pruned to a bud going in the direction the limb was desired. The fruiting wood must be kept as close into the main arms as possible and covered with fruit-bearing shoots. A simple rule used at the High School for boys learning pruning with the peach was never reduce the length of the fruiting wood. On an apricot, leave untouched anything shorter than 9ins.; over 9ins. reduce back as required. Summer pruning was essential to deal with water shoots, and thin out fruiting wood when too thick. The buds of the apple and pear were different to those of the peach and apricot. Progressive orchardists pruned the orange mainly to get a hemispherical shape and to let the light in to the centre, because fruit grows on the annual wood, and such pruning permitted fruit to grow inside the shape of the tree. The shoots should be thinned out and dead wood removed. **Vines.**—Mr. Paterson illustrated by diagrams the different methods adopted in different districts for treating the special vines in those districts. **Questions and Discussions.**—Mr. Paterson explained the difference between a wood shoot and a water shoot as being the growth from the wood of the previous year as distinct from a long shoot from an older lower limb. Several points

were made clear as to the treatment of a tree that had not been pruned for several years, the main one being that the work of shaping must be done gradually. (Secretary, F. Hurr.)

SOUTH AND HILLS DISTRICT.

The Exhibit staged by the Balhannah Branch of the Agricultural Bureau which was awarded the First Prize of £30 donated by the Royal Agricultural and Horticultural Society and the £5 5s. trophy presented by Cresco Fertilisers Ltd. The exhibit scored 915 points out of 1,000.

CURRENCY CREEK.

June 12th.—Attendance, 8.

FARM EFFICIENCY OF THE TRACTOR.—Mr. G. Holme read the following paper:—"The quality and quantity of the work, its cheapness and the time occupied are all factors which count in the efficient working of a tractor on the farm. The best results will be obtained by working the cultivating implements at the right depth. The tractor also has a reserve power that is lacking in horse teams. The power drives and the tractor gives absolute control of the speeds necessary to make a first class sample of grain. The tractor will work for a period of from 50 to 70 hours before it is necessary to make a complete stop; to change oils, &c. The hours worked depend on one or more men, not the tractor because motor power in its different forms is now looked upon as inexhaustible. With the tractor ploughing can be done for less than 1s. per acre, cultivating and seeding for less, and harvesting for about 1s. per acre. Because it is possible to work "non stop" on a paddock costs are further reduced, because there is no power wasted in stops or starts. With a tractor outfit the land can be worked at the most opportune time, which materially assists in the control of weeds." (Secretary, D. Jeff Gordon.)

FINNISS.

July 10th.—Attendance, 13.

PIG BREEDING.—The following paper was read by Mr. M. Burzacott:—"It pays a farmer who is going in for pigs to breed suckers because he can get the type of pig he requires. If he wants Large Whites he procures the sows and boar, and then breeds from them. When choosing breeding sows, be sure that they are healthy, also select a healthy boar, because if the parents are subject to a disease or deformity the litter is liable to inherit these defects. Great care must be taken to ensure cleanliness, pens should be cleaned out and fresh bedding put in every day. It is not advisable to put too much straw in a farrowing pen until the litter is a few days old, because they are liable to get under it, and the sow will lie on them. The sows sometimes crush the little ones against the wall, and to prevent this put a guard rail 9in. from the wall and just far enough from the floor for the little ones to get underneath. Do not have the rail attached to blocks in the floor, but let into the walls. A good guard rail can be made out of 2in iron pipes. When the little pigs are old enough to eat add crushed grain to the milk, and give them plenty of greenstuff. It is a good plan to have a paddock for them to have a run in and shut them up at night. All grain should be crushed; if a crusher is not available soak it, but do not feed it to the pigs until it has been soaking for at least 24 hours. When the pigs are about 10 weeks old, they are ready to wean. Do not wean too suddenly, keep them from the mother in the daytime and put them with her at night, and lengthen the time gradually until at about 12 to 14 weeks, when they can be taken from the sow altogether. A good lick to supply minerals is 40 per cent. superphosphate, 20 per cent. coarse salt, 20 per cent. charcoal, 5 per cent. sulphate of iron, 5 per cent. Epsom salts, 5 per cent. sulphur, and 5 per cent. soda bicarb." (Secretary, L. Dunn.)

WOMEN'S BRANCHES.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

ANNUAL CONGRESS OF WOMEN'S BRANCHES.

Congress was opened by His Excellency the Governor on Monday, September 11th, at 8 p.m., the following delegates were appointed by their respective Branches. The figures indicate the number of sessions for which attendance cards were recorded:— Miss L. Dennison (5), Mrs. J. Schmerl (3) (Auburn); Mesdames J. Murphy (5), E. Norris (5) (Balumbah); Mesdames E. L. Orchard (4), F. Cummings (5) (Belalie); Mesdames J. C. Dux (4), F. Hicks (3) (Clare); Mesdames W. Redman (4), E. Alder (4) (Coonawarra); Misses Stott (2), F. Huppertz (3) (Eurelia); Mrs. F. Wienert (5), Miss J. Sargent (3) (Gladstone); Mrs. C. Lutz (5), Miss C. Paech (4) (Goode); Miss A. Kennedy (5), Mrs. H. Brooks (3) (Kalangadoo); Mesdames J. White (3), G. Thorpe (3) (Kangarilla); Mrs. G. O. Cook (4), Miss A. Shepherd (4) (Kybybolite); Mrs. D. F. Morrison (4), Mrs. Bowells (4) (Laura Bay); Mesdames A. J. Turner (0), P. C. Cleave (4) (Mangalo); Mrs. K. Warren (2), Mrs. B. Elliot (2) (McLaren Flat); Mesdames H. J. Hutchesson (5), A. J. Schultz (5) (Millicent); Mesdames J. Twigden (5), W. Twigden (4) (Morchard); Misses W. A. Fisher (5), M. L. Kemp (4) (Mundalla); Mrs. F. Jose (5), Miss T. M. Franks (5) (Nelshaby); Mesdames C. Neindorf (5), C. S. Foale (4) (Parilla); Miss M. Ferguson (3), Mrs. M. Simpson (4) (Parilla Well); Mrs. E. J. Lahne (4), Miss J. Halliday (5) (Parrakie); Mesdames F. Kidman (5), I. Carne (5) (Penola); Mrs. P. N. Dowd (4), Miss K. O'Loughlin (4) (Pinnaroo); Mesdames E. Heylen (5), A. Kammerman (5) (Pygery); Mesdames S. Smith (4), G. E. Andrews (5) (Rendelsham); Miss G. Frost (2), Mrs. H. Roberts (4) (Saddleworth); Mesdames J. P. Burchard (4), M. E. Troeth (4) (Tantanoola); Mrs. W. Fogden (5), Mrs. W. Flynn (Taplan); Mesdames B. Daniel (4), I. Hampel (5) (Warramboos); Mrs. A. W. Wilson (4), Miss G. George (4) Wasleys; Mesdames J. Steer (5), H. Pritchard (5) (Wilkwatt); Mrs. G. Hammatt (5), Miss W. Cundy (4) (Williamstown); Mesdames W. R. Blatchford (5), W. R. Jones (5) (Wirrilla); Mesdames M. Hopgood (5), J. Jarrett (5) (Yurgo); Mrs. A. Pfeiffer (4), Miss I. Hasting (4), (O'Loughlin); Mesdames I. Jasper (5), A. B. Knauerhase (4) (Wepowie).

On Tuesday morning Mrs. J. S. Hammatt (Williamstown) was elected President, and Miss E. Lenihan acted as Secretary.

During the various sessions the following papers were read and discussed:—

RUGS FROM RAGS AND THE SCRAP BAG.

[MRS. E. L. ORCHARD, Belalie.]

To make something out of discarded material appeals to most women folk, and few revivals are giving greater pleasure than that of rug making. Needlewomen, skilled or not, who have time and patience at their disposal can turn waste material into really beautiful and durable rugs, the great charm of the work being in the fact that while the beginner can readily make a satisfactory floor mat a clever worker with a good sense of color schemes can make rugs of surpassing beauty.

At a competition held early this year in Melbourne in aid of a blind institution, there were 137 hooked rugs exhibited—some made by blind workers—and among them rugs that had been 30 years in constant use and looked almost new. Hooked rugs on canvas foundation are the most fascinating of all home-made rugs.

Hessian can be used for a backing; it is cheaper than canvas, and very suitable for working fine designs such as flowers and for small geometrical patterns. Hessian by the yard or cut from bran bags should be washed before using to remove the natural unpleasant odor. Rug canvas is very stiff and open for a beginner, and the squares are easy to follow with any pattern that can be divided into corresponding squares, though at first it may make the worker's fingers tired and sore.

PLATE 1.

- A. Tufted rug. Small strands of scoured wool, hooked through canvas.
- B. Nursery rug. Old material hooked into a bran bag and not clipped.
- C. Dyed wool hooked rug. Been in use 23 years.

ALL that is required to make a hooked rug is a foundation, a No. 00 steel crochet hook, a pair of large, broad bladed, sharp scissors, and a suitable quantity of well washed old clothes.

Woollen material keeps its warmth to the last thread, and need not ever be wasted. Any article that can be cut into strips will make hooked rugs of almost everlasting wear.

Cotton and silk can be used, but it is not wise to mix the materials as they have different wearing qualities. New materials can be used in conjunction with old, but it is best to wash and sometimes fade them before cutting or tearing into strips. Old material must be cut for it will not tear straight; the widths may not be regular, and the result would be uneven work. Generally speaking, a rug wears best if made entirely of woollen or entirely of cotton goods, though they can be mixed and a little silk or artificial silk introduced, but never in large patches, because silk tends to break away and cotton has to be treated differently to get the best results.

It is a good plan to design the rug first, and for a first attempt a simple pattern in lines and squares is best. With hessian for a backing very wide turnings must be taken or it will fray and spoil the appearance of the finished article. When using dark materials for a border, first of all bind the selvages with the same color bias binding, though for a light border it is not necessary except to make the edge stronger. (Plate 2, Fig. D.)

A very comfortable rug can be made from scoured wool. (Plate 1, Fig. A.) This tufted rug was made on canvas foundation, the wool having been prepared as follows:—The sheepskin was cut into strips for easy handling, soaked in cold soap suds for 12 hours, taken out and soaked another 12 hours in fresh soap suds, then scoured thoroughly in hot soapy water, rinsed in clear warm water, and dried. Then the wool was combed and cut off in small sections as the combing proceeded. The tufts were then looped through the canvas.

The Nursery Rug (Plate 1, Fig. B) is made on branbag foundation from strips of old woollen materials pulled through with a latch hook and left unclipped. Green skein rug wool made the hooked doormat (Plate 1, Fig. C), and it has been in constant use for 23 years. The wool was cut in 8in. lengths, doubled, pulled through canvas, the ends slipped through the loop and knotted. This is the oldest type of hooked rugs made in England many years ago.

For the door slip (Plate 2, Fig. C) the materials to be used should be prepared by cutting or tearing into suitable strips, the thickness determining the width—new flannel about $\frac{1}{2}$ in. and cashmere 1in. To test, hold strip under canvas, put hook through top of canvas, and pull up end of strip about 1in. Insert hook in next space, and draw loop of material about $\frac{1}{2}$ in. to $\frac{3}{4}$ in. through to top, and if loop fills space in canvas without being slipped or dragged through it is the correct width, and in testing the stitch is learned. Always commence a strip in the same space as the end of the previous strip, all ends being sheared off in the final clipping. The back must be perfectly free from ends, and each loop, if the strip is of correct width, will help to keep its neighbor in place.

On Plate 2 is shown a hearth rug (Fig. A) and a desk rug (Fig. B), both made from warm woollen material. Fig. D shows a rug in the course of construction—wool and cotton materials being used—and the edge of canvas bound with bias binding.

CROCHETED AND KNITTED RUGS.

Artificial silk, printed cottons, or any similar material can be used in a plaited rug, as Fig. A in Plate 3.

Cut old frocks or dust coats into pieces 8in. to 10in. wide, and plait firmly. The pieces can be cut 3in. or 4in. wide, but as all edges must be turned in to tidy the work, this is difficult in a narrow strip. Also with wide pieces the work is thicker, and grows more quickly if the plait is wide. Plait the strips closely and evenly—just as hair is plaited—with three strands, joining on more material at irregular intervals to prevent bulkiness. As soon as 3ft. or 4ft. in length are plaited commence shaping, and sew with strong thread. In order to keep the work perfectly flat it should be sewn on a table, and very close stitches used to

prevent buckling. Narrow each strand for the last few inches and finish off neatly. Face back a few inches with something firm, thus giving extra strength to the edges, as it is always the edge that wears first.

Silk stockings, bloomers, and singlets or any article in Kayser, celanese, &c., wear can be used after they are discarded as wearing apparel by cutting into strips and crocheting or knitting in oblong or round shapes, and will make useful bedside rugs.

For a crocheted rug commence by cutting off the worn feet of stockings and beginning at ankle cut around leg into one long strip $1\frac{1}{2}$ in. to $2\frac{1}{2}$ in. wide 5 yds. to 8 yds. in length, depending upon the thickness of the stocking. Wind each into a ball and arrange colors, then with a large bone crochet hook commence

PLATE 2.

- A. Hearth rug. Hooked strips of old materials and clipped.
- B. Desk rug. Hooked old materials, mostly dark.
- C. Door slips. Back kept smooth to save lining.
- D. Hooked rug in course of making; edge bound with strip of material.

with enough chain to form centre of rug, work around with double crochet, increasing evenly at corners until size required. To make an oval, increase irregularly at ends, and line with firm materials.

To make a knitted rug (see Plate 3, Fig. B) cut the stockings, &c., into strips in the same manner but only $\frac{1}{2}$ in. wide, cast on to No. 10 bone needles one stitch and increasing by one stitch each turn until five stitches are on, and continue those five stitches until long enough to form centre of rectangular mat. Shape each

turn, and sew strips together with invisible stitches as the work proceeds, arranging colors to form a design or jumble colors as they come, and dye the mat when knitting is completed.

PLATE 3.

- A. Platted rug. Worn coats and frocks cut in strips.
- B. Knitted bedside rug. Old celanese garments.
- C. "Bitea" rug. Lengths of odd knittings sewn to foundation.
- D. Knitted door slips. Short pieces of material knitted with macrame thread.

A pretty finish for a mat of this kind is a flat flannel scalloped edge about $1\frac{1}{2}$ in. wide, and then lined with firm cotton material. These rugs can be cleaned by washing in Lux or soft soap, the same as if the material was still in its original form of stockings or singlets.

There are several other interesting ways of using old materials and also new pieces from the scrap bag, and left-over pieces of knitting wools.

Ravelings from old wool sweaters, socks, scarves and so forth may be used to advantage to make a charming Knitted "Bitsa" Rug. "Bitsa" because it is all bits of wool, odd lengths of new and joined lengths from old knitted garments, the faded colors often making the prettiest rugs. First cut a piece of hessian, ticking, or any firm material suitable for foundation into the shape and size desired, allowing about 2in. all around for a hem. Short size 4 knitting needles in wood or bone are most suitable for use. Cast on six stitches in one or mixed colors—two or even three threads may be used—and if very thick use only five stitches and knit back and forth, always slipping the first stitch until the strip is the required length and about 1in. in width. Fold lengthwise, and top sew to foundation—being careful to sew firmly both edges—cut through centre lengthways with sharp scissors. The cut edges will not ravel. Allow $\frac{3}{4}$ in. to $\frac{1}{2}$ in. between each row beginning at centre to form a round or oval rug, and at one end for a rectangular one. The result is a lovely, deep pile rug that will brighten any bedroom or den.

In this "Bitsa" rug (Plate 3, Fig. C) some strips of machine-knitted wool were stitched in between rows of hand-knitted wool, and show a good method of using discarded cardigans, &c.

Another way of using woollen and wool and cotton pieces—dressmakers' and tailors' scraps are ideal—is to knit with a background of strong thread (Plate 3, Fig. D), and some authorities claim they wear longest of all home-made rugs. The idea is to knit in strips or squares planned in striking designs and attractive colors, and they are very pleasing in effect. Twine about the thickness of knitting cotton but of a firm twisted variety, No. 12 steel knitting needles, cardboard gauge 2in. wide, sharp scissors, and a box of assorted materials arranged for convenience in separate compartments are necessary. The cutting of the cloth into *regular* lengths is essential to the finished appearance, and does away with any clipping afterwards, which is the hardest part of the work. Cut pieces 2in. long and $\frac{1}{2}$ in. wide, and if material is thin cut it wider but the same length, and fold as you work. The easiest way for working a rug made in this manner is to knit in strips and top sew together afterwards.

For comfortable handling cast on 13 or 15 stitches, knit one row, turn, knit first stitch, and lay one piece of material a little more than half way across thread with long end towards worker; knit second stitch, and place long end over and knit next stitch. Insert another piece of cloth, and repeat to end of row. Always work with pile of rug away from you. Knit return row without putting in any cloth. Nine strips of 15 stitches 14yds. long will make a very serviceable hearth rug. It is advisable, after the method has been mastered, to add one stitch each edge for sewing on to prevent buckling. Face the rug underneath for about 2in. to ensure it lying flat.

For the Dollar Rug (Plate 4, Fig. A) the foundation used was part of an old skirt; the border, saddle bag tweed trousers, and the gay pieces from the scrap bag. The gauges used for the discs were $2\frac{1}{2}$ in., 1 $\frac{1}{2}$ in., and 1in. across respectively—the 1in. discs being cut from the centre of the $2\frac{1}{2}$ in. pieces. After cutting the discs the next step is to arrange them on the background, and the button-hole or blanket stitch with contrasting thread. By having between the rug and the hessian back a layer of worn-out hand knitted pullovers, the rug will be made extra thick and warm for the feet.

If only a small quantity of material is available a good plan is to cut in $\frac{1}{2}$ in. strips, thread into a bag needle, and over sew into hessian. Mark a conventional design on the hessian in charcoal or chalk and then, taking long stitches on top and short ones underneath, sew the materials into hessian in the manner of satin stitch in embroidery. Line with another piece of hessian, and bind with a firm piece of contrasting or matching material, and the result is a sail stitch rug, as Plate 4, Fig. B.

Another way to use odd lengths of wool is in making a cross stitch rug (Plate 4, Fig. C). Small mesh canvas and four-ply wool were used, three rows of cross stitch worked over each other, the two top rows being cut through after working.

All wool rugs are vastly improved by cutting the surface loops; this is called clipping or shearing (Plate 4, Fig. D); but cotton mats look best if left in the loops, for if they are cut they go flat with wear, whereas the woollen materials remain soft and springy. These rugs should not be lined as they are fairly heavy

PLATE 4.

- A. Dollar rug. Discs of colored material sewn to a backing.
- B. Sail stitch rug. Narrow strips of thin material sewn in stem stitch into hessian.
- C. Cross stitch door slip.
- D. Hooked door slip, showing part not clipped.

and closely worked, and a lining would hold the dust. To clean them beat against a wall and brush with a straw broom or clean with a vacuum cleaner, and if necessary sponge or wash in Lux or soft soap and dry in not too strong a wind.

Some of the last-mentioned types will not wear as long as hooked or knitted rugs but they do not take so long to make, nor use the same quantity of material. However, they are all beautiful to look at and comforting to use, and the feeling of satisfaction experienced in having made something out of waste material is very gratifying.

THE USES OF WHOLEMEAL.

[By Miss K. O'LOUGHLIN, Pinnaroo.]

Wholemeal is wholesome and economical. It makes a very good porridge for breakfast, and can be used for bread, scones, biscuits, puddings, and cakes.

For bread take one-third wholemeal and two-thirds flour, make in the usual way only mix a little more moist, and add about 1 tablespoon of treacle when mixing, to make six 2lb. loaves.

For scones they, like the bread, are better mixed a little on the moist side, and a teaspoon of honey added when mixing. Any puddings, cakes, and biscuits that have honey or treacle in them are nice made with half wholemeal and half plain flour.

The following recipes have been tried and proved:—

PUDDINGS.

Marmalade.—2 cups of wholemeal, 1 cup of marmalade, 1 tablespoon of butter or lard, 1 teaspoon of carbonate of soda dissolved in 1 cup of cold milk. Steam for 4 hours, and serve with egg custard.

Ginger Pudding.— $\frac{1}{2}$ lb. wholemeal, $\frac{1}{2}$ lb. suet, 1 teaspoon ginger, 1 teaspoon carb. soda, $\frac{1}{2}$ cup milk, $\frac{1}{2}$ cup treacle, 1 egg. Mix flour, suet, soda, and ginger. Beat egg, add to milk and treacle, mix into dry ingredients, put in well-buttered mould, and boil 4 hours. Serve with wine or custard sauce.

Wholemeal Pudding.—2 eggs (beaten) and their weight in butter or lard and self-raising wholemeal, the weight of 1 egg in sugar, 2 tablespoons jam. Steam for 3 hours.

CAKES AND BISCUITS.

Fruit Cake.—1lb. sugar, 1lb. butter, 1lb. currants, 1lb. raisins, 9 eggs, 1lb. lemon peel, $\frac{1}{2}$ doz. dried figs, $\frac{1}{2}$ lb. almonds, 1 nutmeg, essence of lemon and rind and juice of lemon, 1 tablespoon of rum, 8ozs. wholemeal, 8ozs. self-raising flour. Beat butter and sugar to a cream, add eggs, then fruit gradually, lastly wholemeal and flour. Bake in moderate oven for 4 hours.

Cream Buns.—1 cup cream, 3 eggs, 1 cup sugar, $1\frac{1}{2}$ cups self-raising wholemeal, $1\frac{1}{2}$ cups self-raising flour, bake in papers. When cooked and cold lift pieces out of centre. Fill with whipped cream, and dust with icing sugar.

Ginger Buns.—2 tablespoons butter and $\frac{1}{2}$ cup sugar beaten to a cream, 1 egg, $\frac{1}{2}$ cup milk $\frac{1}{2}$ cup treacle, 1 teaspoon each of ginger and cinnamon, $\frac{3}{4}$ cup flour, $\frac{3}{4}$ cup wholemeal, lastly add $\frac{1}{2}$ teaspoon of carb. soda dissolved in a little boiling water. Bake in papers. When cooked and cold, lift piece out of centre, put in some whipped cream, place piece back, and dust with icing sugar.

Ginger Nuts.— $\frac{1}{2}$ lb. wholemeal, $\frac{1}{2}$ lb. flour, $\frac{3}{4}$ lb. butter, $\frac{1}{2}$ oz. ginger, 1 teaspoon carb. soda, $\frac{1}{2}$ teaspoon salt, 3ozs. dark sugar, $\frac{1}{2}$ lb. treacle, 2 tablespoons milk. Bake in moderate oven $\frac{1}{4}$ of an hour.

Ginger Cake.— $\frac{1}{2}$ lb. butter, 1 cup sugar, 1 cup treacle, 1 cup sour cream, 2 cups flour, 2 cups wholemeal, 2 teaspoons carb. soda, 1 tablespoon ginger, 3 eggs, rind of 1 lemon, lemon peel or almonds to taste. Bake 1 hour in moderate oven.

Wholemeal Biscuits.— $\frac{1}{2}$ lb. self-raising wholemeal, $\frac{1}{2}$ lb. self-raising flour, $\frac{1}{2}$ lb. sugar, $\frac{1}{2}$ lb. butter, 2 eggs. Mix butter and sugar to a cream, add eggs well beaten, lastly flour and wholemeal.

A SENSE OF VALUES.

[By Mrs. A. ELLIS, Balumbah.]

We are all satisfied that something is seriously wrong with the world, but few people will admit the possibility that perhaps the trouble lies within themselves. We spend our lives struggling for the shadow only to find we have somehow missed the substance.

Every wise business man takes stock periodically and finds out exactly where he stands, corrects his errors, revises his methods, and determines his direction and policy in order to render the best service possible to prove his efficiency and to ensure success.

We women must also find out whether we are on the right track, whether we assess things at their true value or whether we can improve conditions in our own sphere which will be reflected in the welfare of the community generally.

I will enumerate briefly under headings a few things which are worthy of consideration.

HEALTH.

To be happy one must be healthy, and since the task of feeding and clothing humanity falls to women, they should know how best to perform this task. In this paper, I am dealing with problems that confront farm women generally, and bushwomen in particular.

Many women starve to send as much cream or butter to the market as possible, and some stint their families in so doing. A wiser policy is to use as many home products as possible and sell only the surplus. It is not economy to sell at the present low prices, which are less than half the real or nutritive value of the commodity, and then to have to pay double the value for a substitute. Give the children plenty of butterfat and save on cod liver oil. Study food values. By wise feeding, a mother builds up the constitution of her child, which is infinitely preferable to building up a bank balance.

REST.

Do we realise how important it is to have plenty of rest? Women, who from a false sense of duty make slaves of themselves, become irritable and moody, and their homes are anything but peaceful. Many women are reputed hard workers

Bone Manure

when they are merely slow workers. They could do their work with half the energy if they had *method*.

CLOTHES.

With regard to clothes. Secure good value by buying good materials; it is possible to be fashionable without being a slave to fashion. Do not restrict the body in any way, but let the garments hang from the shoulders. To be well dressed is to be suitably dressed.

WORK.

Women appear to follow custom blindly in the matter of work. How they forge and hug their chains! They cannot resist acquiring possessions which, in many cases, really own the women. Some women long for big houses packed with furniture, and then having acquired them, spend weary days cleaning them. To eliminate non-essentials seems an impossibility for some women. The household gods must be revered. Conditions outback do not foster this trait during the pioneering stage.

There is much vagueness regarding the value of women's work and place in the world. Prior to marriage, their value to the community is recognised as typists, shop girls, dressmakers, nurses, &c., and they receive pecuniary recognition, but immediately a girl marries she loses her status and becomes a dependant to be supported, or even an unpaid farm drudge in some cases, though for income tax purposes her services are valued at £30 per annum. I am not advocating wives should be paid, but we should all realise the value of women's work, particularly in caring for the nation's best asset, the children. How strange it is that we regard caring for people in sickness as a profession, while caring for and maintaining people in health is classed as servitude. To know one's job, to recognise one's sphere in life, to pursue and enjoy it, in a word to "belong," is to get the best out of life, which is generally equivalent to what we put into it.

HOMES.

In some bush localities, homes seem to "happen." Wherever the pioneer pulls up his team there he dumps his chattels and thinks he might put up a bit of a shack. The sense of values in the matter of housing seems almost non-existent outback. Frequently motor cars are better housed than are the wife and family. Women should insist on having some part in designing their homes. A hut made of bags and kerosene tins could face the right way and be placed in the most convenient position, with the best view obtainable. A woman spends most of her time indoors, and some comforts and conveniences are most essential. Building in the centre of the block is a minor detail and not altogether necessary. A small garden, well kept, is of far greater value than a garden too large to be kept in order comfortably.

SPORT.

A certain amount of sport is necessary and desirable, but when the youthful mind is occupied with that only it becomes an obsession and is detrimental to work. Try and inculcate a love of reading in children. While you have books on your shelves you always have friends; you can enjoy the works and benefit by the experiences of the world's best scientists, philosophers, authors, &c.

Beware of class distinction in social activities; this is apt to creep in as prosperity advances. Do not allow all the labor of providing amusement to fall only upon the mothers. See that each member of a family or organisation takes his or her proper share.

EDUCATION.

There is much misconception regarding this important subject. Even in this age, parents vainly imagine that education is a passport to a well paid job with little work attached. They seek for their children a "respectable" job, where

a collar and tie is necessary, and which they deem far superior to a shirt sleeve-job. Rather would it seem that honest labor and beautiful craftsmanship are despised. We must not overlook the fact that people's character and underlying humanity are more important than their occupation. To know one's self and to know one's job is an education in itself. Economic considerations should not have undue prominence when one's role in life is concerned: Discussing the difficulty of wheat growing at a profit to-day with a farmer, I asked him why he continued to grow wheat at a loss. "I have got to grow wheat," he replied, "I can't help it, it is my job." It is a wise man who knows his own job.

PUBLIC AFFAIRS.

A much debated question is whether women should restrict their activity to home duties or take an intelligent interest in public affairs. I believe that women should foster and cultivate a sense of responsibility outside their own homes. It is a duty they owe to themselves, their children, and the future generations to understand economic principles. The problem of war should occupy the minds of all women. Women bear and rear children, expending much trouble and anxiety in order to train them to become worthy citizens. As a nation, we raise innumerable barriers against foreign trade, and then wonder that international relations are not more harmonious. With amazing humility or indifference many people are content to leave the most vital affairs in the hands of a few people without giving any thought whatever to their significance. We must do our own thinking and benefit by past experience. Right thinking is the prelude to sound action, and reconstruction should and must begin from within.

RECIPE FOR CARAMELS.

During the women's session of the Annual Congress, Mrs. Eggers, of Wa-leys, read a paper, "Sweet Making." In the discussion that followed, Mrs. L. Redman, of Coonawarra, gave this recipe for making caramels, which is published at the request of the delegates:—One large breakfast cup of sugar; one level tablespoon of plain flour; stir well together, and then add piece of butter the size of a hen's egg; two tablespoons golden syrup; half cup milk. Boiling quickly, this takes about half an hour to cook, stirring all the time. Test by dropping a little into cold water, and if there is a soft ball, immediately pour out and leave to set. Before quite hard, shape the squares with a knife. To keep, wrap in paper.

OTHER ADDRESSES.

Valuable hints on home nursing were given by Sister Bottrill of the District Trained Nursing Society.

"Milk as a Food" was the subject of an address by Miss E. Campbell, Inspector of Domestic Arts in the Education Department.

Miss Campbell was presented with a set of cut glasses and a dictionary by Mrs. Hammatt as an appreciation of her work for education and for Women's Branches of the Bureau.

Mr. D. Hart, of W. H. Bruce, Limited, gave a demonstration of poultry dressing.

Delegates also visited Walton's Confectionery Factory, the Waite Agricultural Institute, and inspected the Home School, conducted by Dr. Ethel Hillier at South Terrace.

RESOLUTIONS.

The following resolutions were carried:—

"That this Congress strongly protests against any further imposition on the farmer by way of a sales tax on flour; rather would we strive for decreased costs of production."

"That a flat rate be made on perishables on South Australian railways and boats."

"That the Agricultural Bureau ask the Royal Agricultural and Horticultural Society to supply free of cost the material for staging displays of Branches at the Royal Show."

"That the Advisory Board be asked to consider the appointment of a State organiser for the Women's Branches of the Bureau, or failing that a woman representative on the Advisory Board."

"That this Congress of Women's Branches associates itself with the Men's Branches in asking the Government to reconsider its decision to abolish free passes to delegates to the Annual Congress."

BELALIE (Average annual rainfall, 17.71in.).

July 11th.—Attendance, 36.

Mrs. Wedding gave an interesting talk on "Soap Making," and in the discussion that followed it was stated that sugar added to the soap mixture helped to keep the soap from getting too hard. The best soap was made by melting the fat first, then adding caustic soda dissolved in water. Too much water used in boiling left a quantity of water under the soap when set. Resin should be powdered before adding to fat. Lux, borax, and olive oil should be added when the soap had nearly finished boiling. The annual report was read, and officers elected. (Secretary, Mrs. A. Cummings, Jamestown.)

COONAWARRA.

July 19th.—Attendance, 15.

CITRUS FRUITS AND THEIR USES.—Mrs. Allder read the following paper:—"The growing of citrus fruit during the last 10 years has become a leading primary industry, and the annual production is now so great as to make it necessary to find markets for the fruit. New Zealand has been one of our best markets; thousands of pounds worth of fruit being exported there yearly, but this year New Zealand has prohibited the entry of citrus fruit from Australia into their country, owing to disease in some of the States; it being necessary to ship the surplus to England, where the prices are so low that the Government have offered to pay the growers the cost of production for all they ship overseas. *What You Can Do with a Lemon.*—

(1) Heat thoroughly before squeezing to get more juice. (2) It is good for cleaning brasses; put a little whiting first on the article to be cleaned, then rub over with lemon. (3) New shoes that are difficult to polish should be rubbed over with a lemon and then left to dry. (4) Sprinkle lemon juice over a fruit salad, this will prevent it from turning dark. (5) A few drops of lemon juice added to rice when cooking will make it a lovely white. (6) A few drops of lemon juice on a very bad corn will relieve the pain. *Lemon Jelly Filling.*—Grated rind and juice of two lemons, three tablespoons sugar, two cups water, brought to the boil, then thickened with one tablespoon cornflour. Stand all to cool, spread between sponge, and sprinkle cocoanut on top. *Lemon honey.*—½lb. white sugar, 2ozs. butter, two eggs, grated rind and juice of two lemons. Put altogether in an enamel saucepan, stir over the fire until it thickens. Put in jars, keep for cheese cakes, sandwiches, and spread on bread instead of butter. The juice of a lemon in the rinsing water when washing the hair gives a nice gloss to the hair and makes it soft. *Lemon Peel.*—1lb. dry peel, 1½lbs. sugar, half a cup of water. Soak peel three days in brine, then boil twice in clean water about 20 minutes, or until tender. Have syrup boiling, drop peel into it, simmer 20 minutes each day until it candies. *Treatment for Cough.*—Well mix the juice of a lemon, 1oz. of glycerine, and one tablespoon of honey. Take a teaspoon night and morning, or more often if necessary. *Cough Mixture.*—One cup honey, half a cup olive oil, juice of a lemon. Bring all to the boil, then bottle. Take a teaspoon of the mixture when necessary.

ORANGE RECIPES.—*Orange Marmalade* (one day).—4lbs. oranges, 8 pints water, 12lbs. sugar. Slice the oranges, cover with water, stand all night, and boil until tender. Take off fire and cool, boil again and add the sugar. Boil until it jellies. *Orange Ju Jubes.*—Take one cup of loaf sugar, half a cup orange juice, and quarter teacup cold water. Boil water, sugar, and three dessertspoons of gelatine together for 20 minutes; allow to cool gradually. Stir in the orange juice, and when well mixed pour into a flat greased tin. When cold cut in small pieces, roll in icing sugar. *Orange Layer Cake.*—6ozs. butter, one pinch salt, 6ozs. sugar, one flat teaspoon cream of tartar, four eggs, half flat teaspoon carbonate of soda, one grated rind of an orange. Cream butter and sugar, beat eggs well, and add gradually, beating well and keeping mixture smooth. Add the thinly grated orange rind. Sift

THE PRINCIPAL,

Agricultural College,

ROSEWORTHY.

together flour, salt, soda, and cream of tartar, and mix well until smooth and soft. Put the mixture into two well greased sandwich tins. Bake about 30 minutes.

Orange Filling.—Beat the grated rind of a small orange with 1oz. sifted icing sugar, add 1oz. butter, and when well mixed add one tablespoon orange juice and enough sifted icing sugar to make a soft, creamy consistency. *Orange and Lemon Jam*.—Four oranges, four lemons, 2½ quarts water, 6lbs. sugar. Cut up and stand all night with water. Boil one hour, then add sugar and boil about 1½ hours, or until it sets. Boil quickly.

CITRUS RECIPES.—*Sweet Orange Marmalade* (Mrs. R. Redman).—6 sweet oranges, 6 lemons, 12 quarts water. Cut fruit into thin slices and stand in water overnight. Next day boil until tender, add sugar, and boil until it jellies. *Lemon Pudding*.—1 cup sugar, beat to a cream with 1 tablespoon butter. Add 2 tablespoons flour, juice and grated rind of 2 lemons, 1 cup milk and beaten yolks of 2 eggs. Just before pouring into dish fold in the stiffly beaten whites of eggs. Set the dish in a larger one filled with hot water; bake slowly one hour. *Orange Date Cake* (Mrs. Reschke).—4ozs. butter, 8ozs. flour, 4ozs. sugar, ½ level teaspoon carbonate soda, 2 eggs, 2 or 3 tablespoons orange juice, 4ozs. stoned dates, grated rind 1 orange, candied orange peel, 2 level teaspoons baking powder, a little milk. Bake about three-quarters hour. *Lemon Meringue Pudding* (Mrs. Childs).—1 pint water, 1 cup sugar, yolks 2 eggs, grated rind and juice 2 lemons, 1oz. butter, 2 heaped tablespoons cornflour. Put water, sugar, beaten yolks, rind, and juice of lemons and butter in saucepan, bring to boil. Mix cornflour to thin paste with cold water and add to boiling ingredients, boil a few minutes, then pour into greased piedish. Beat 2 whites to a stiff froth, add 2 tablespoons sugar, pile on top of pudding. Bake in oven until a pale brown; serve cold. *Dried Apricot-Orange Jam*.—2lbs. dried apricots (washed), 5 medium sized oranges, 8lbs. sugar, 14 cups water. Soak grated rind and sliced flesh of oranges and apricots in the water 24 hours. Boil half hour, add sugar, and boil for another hour or until it jellies. *Orange Foam* (Mrs. O. Skinner).—2 cups hot water, juice 2 oranges, ½ cup sugar, ½ lemon, 2 tablespoons cornflour, 3 eggs. Boil water, add sugar and cornflour mixed with water; stir and cook five minutes. Add fruit juice. Whip whites stiffly and pour over mixture when cool. Beat until white and foamy. Make a soft custard of 1 pint milk, 2 tablespoons sugar, ½ tablespoon vanilla, yolks of the 3 eggs. Pour over the orange foam. *Citron Conserve* (Mrs. W. L. Redman).—Cut citron into small blocks, removing seeds. Cover with water; stand all night. In morning pour off and cover with fresh water and stand until next day. Strain off; add fresh water. Boil gently half hour; stand all night. Next day to every five cups pulp add 6lbs. sugar; boil one hour or until clear. *Navel Orange Conserve* (Mrs. W. L. Redman).—Slice finely navel oranges and add 1 pint water to each pound fruit. Boil three-quarters hour or until soft. Measure and add 1 cup sugar to 1 cup fruit and add the juice of 2 lemons to every 3lbs. fruit. Boil three-quarters hour. *Lemon Cheese* (Mesdames W. L. Redman, Webber, and Childs).—½lb. butter, 1lb. sugar, 6 eggs, rind of 3 and juice 2 lemons. Put ingredients into pan. Simmer until the sugar is dissolved and it begins to thicken like honey. Pour into jars and cover closely down. This will keep for a very long period. (Secretary, Mrs. F. Skinner.)

EURELIA (Average annual rainfall, 12.87in.).

FISH RECIPES.—Paper presented by Miss C. Stott:—“Fish affords a supply of easily digested nourishment at a very small cost; it is therefore a most valuable article of food. Fish is not so nourishing as meat, but it contains minerals, such as phosphates of lime, soda, and potash, which are useful to form and solidify bone. Fish contains a large percentage of water, and when provided as the chief dish for dinner, it should be followed by a substantial pudding. See that the fish is fresh and on choosing them see that all fish are well covered with scales, the gills red, eyes bright and prominent, and the flesh firm to touch. White fish are the most digestible, though salmon and herrings contain the most nourishment. All fish are very unwholesome when out of season and should not be eaten; the wisest plan is to buy the fish that is cheapest, as this will be that most plentiful and consequently in season. Whiting is the most delicate and easily digested of all fish, and on that account is named the chicken fish. Salt fish should be soaked for two hours in water. Flathead is a dry fish, and should therefore be stewed or stuffed and baked. Bream, schnapper, and cod are the best to boil. The eyes should be left in the fish when they are to be boiled, but they should be removed for baked fish. A fish kettle is most convenient in which to boil fish, being fitted with a strainer with which the fish can be lifted out without breaking. Have the kettle three-quarters full of boiling water. The water that fish is boiled in should be as salt as the sea; the water must never be allowed to boil once the fish is put in, but allowed to simmer gently until it is done. When dishing up be careful to drain the fish well, and lay it on the dish without breaking. *Baked Whiting*.—Method—Skin and fillet the fish and lay in a basin

of salted water for 15 minutes. Take out and dry in a cloth; sprinkle with lemon juice, a little salt, and a pinch of cayenne pepper, and wrap in buttered paper. Grease a baking dish, put in the fish, and cook gently in a fairly hot oven 10-15 minutes. Serve with white sauce. *Fried Smelts*.—Dry the fish by rubbing a little flour over them; dip them in egg and fine bread crumbs, and fry in plenty of very hot fat. Drain on a piece of white paper and serve with thin bread and butter and cut lemon. The smelts should be dry and crisp and a nice golden brown." (Secretary, Mrs. E. Wall.)

MANGALO (Average annual rainfall, 14in. to 15in.).

July 12th.—Attendance, 15.

BREADMAKING.—Mrs. A. Lathlean read the following paper:—"Sift 8 full sifters of flour in a clean dry dish, 2 breakfast cups of yeast, and 5 pints of warm water—the temperature 90deg. in cold weather and 75deg. in warm weather. Dissolve 1 tablespoon of salt in the water. Mix a dough, kneading it thoroughly, and set it aside in a warm place to rise, which will take from 8 to 9 hours. When it has risen to the top of the dish, push it down and allow it to rise again. After it has risen the second time, mould and put it into the tins, and let it rise level to the top of the tins. Then put it into a really hot oven to bake. I allow 1 hour for a 2lbs. loaf and a little longer for a larger loaf. After it has been in the oven $\frac{1}{2}$ an hour turn the bread around. This quantity makes seven 2lb. loaves. I favor setting bread over night and baking next morning." (Secretary, Mrs. F. Coles.)

McLAREN FLAT.

[Paper read by Mrs. R. Elliott.]

July 5th.—Present: 16 members.

BACON CURING.—"The Berkshire pig used to be the favorite breed, but nowadays a longer pig is desired to produce leaner meat. A Berkshire is most difficult to scrape on account of its black hair, but the Mid-York or Tamworth has a better colour skin. The pigs should be regularly fed on good wholesome food. If a good run is provided they will not require much attention until topping up for slaughtering, then they should be put into a yard, kept as clean as possible with a dry, warm sty, and feed on milk, pollard, peas, barley, or wheat. They should have sufficient to eat, but do not put too much food in the trough, or it will go sour and be wasted. The latter has a tendency to make the flesh soft. Pigs that are to be killed should be kept without food for 12 or 14 hours, and in no case should they be driven or heated in any way just prior to killing. The carcass should hang in the air overnight and allowed to set before cutting up. Have the tank ready to put the meat in. If a slate or concrete tank is not available, a sheet of galvanized iron flattened out and turned up all round will serve the purpose. As the carcass is cut up, the portion can be laid out in the tank, flesh uppermost, and lightly rubbed with saltpetre and salt. This brings out the blood which should be drained off next day and thrown away. Again rub the meat with salt and drain it the following day; if free from blood, the pickle can be poured over it. The pickle is made as follows:—To salt a pig weighing about 200lbs.:—7lbs. salt, $\frac{1}{2}$ lb. saltpetre, 2lbs. white sugar, 1 packet mixed spice dissolved in about 4galls. of water; the brine should be strong enough to float an egg. The meat must be turned every day and kept moist. The sides of bacon will be ready to come out of the pickle in a fortnight, but the hams require a week longer; they may then be washed and hung up to dry. In a few days it is ready for smoking. Always retain the same pickle. It can be used several times, the older the better; it only requires, when it becomes discolored, to be boiled and clarified, and cooled before using again. When hung in the smokehouse, hams and fitches should be placed as close as possible without touching. Hang them with string or cord, because wire hooks are apt to rust and leave a mark on the rind. The smoke must be cool, without any flames. Allow the sawdust to smoulder and cause a good quantity of smoke for 24 to 48 hours. Care should be taken as to the kind of sawdust. Some wood is highly flavored, and will taint the meat. Deal should *not* be used."

BUTTER-MAKING.—Paper read by Mrs. W. Oakley:—"Butter is a valuable food, and should be consumed more. It is rich in vitamins, and is easily digested. Children especially should be encouraged to eat plenty of butter. It is a very necessary and helpful food for the development and growth of the body. To produce good butter, care must be taken that the cows do not eat any weeds or food that may taint the milk. All utensils in the dairy must be kept perfectly clean, and after they are washed, rinsed in boiling water. Allow cream from the separator to cool before mixing with other cream. Never run warm cream from the separator on to cold cream; stir in later, with a little salt added. To ensure best results, cream should not be kept more than two days before churning in summer and four days in winter. Cream to be churned should be about 60 degrees F. If this temperature is obtained, and if the cream is fairly thick,

the butter will be churned in a few minutes without any trouble. If the cream is cold, stand in a dish of warm water. Once churning has commenced it should be continued until the butter has become a solid lump; then the buttermilk should be immediately strained off. It is important that all buttermilk be thoroughly washed out of the butter. The water is then poured off, and some clean water added. This process is continued until the water comes away clear. Butter will not keep good for long if any buttermilk is left in it. After washing, add salt, stand aside for a while to get firm, then work all water out. When free from moisture, form into pounds, lay the paper on it, fold over sides, turn with pats, and neatly fold in edges. Butter made in this way will keep in good condition for a fortnight."

BUTTER-MAKING.—Mrs. B. Smith read the following paper:—"During the making of butter cleanliness is the most important part of the process. The flavor depends on how the cows are fed and how the cream is tested. Cows need a liberal supply of bran in their diet; this helps to give the butter a nutty flavor. Also, they should be given plenty of green feed and exercise. All utensils must be washed and scalded after use. If there is no dairy, a hanging safe or cooler should be used for keeping the butter in, and this is better kept in the open air, thus avoiding contact with vegetables, meat, fruit, or the smell of cooking, etc., all of which spoil the flavor of the butter. Freshly separated cream must not be mixed with cold cream until it too has become cold. Scald the churn and rinse with cold water before putting in the cream. Churn until all the butter has collected into large lumps, and then churn a little longer. Pour off buttermilk, and then rinse in three different waters, churning well each time. After the third rinsing, churn for 5 minutes without any water. By doing this most of the water will be worked out of the butter. Turn out into a shallow enamel bowl and knead well with a piece of clean linen which has been scalded and dipped in and wrung out of cold water. This will absorb the rest of the mixture, which must be all removed before adding the salt. Roll and sift the salt, and add a level tablespoonful to 1lb. of butter. Work the salt well into the butter before patting into shape. If the cream becomes too hard to churn, do not add warm water, but a little luke-warm separated milk will be found a great help if mixed with the cream, and will also prevent streaky butter. When once the butter-making has been started, do not leave it stand; this may also cause the butter to be streaky. To make a good butter it is most important to churn three times a week in summer and twice a week in winter." (Secretary, Mrs. D. Elliott.)

NELSHABY (Average annual rainfall, 17in.).

NOVELTIES.—Paper presented by Miss R. Noble:—"To the dress lover often a novel arrangement of belt or neckline, or some novel finish, will make a dress just what one desires. A post and rail of narrow black and white machine-stitched bands of crepe de chene makes a novel and delightful finish to the cape of a black crepe de chene dress, the sleeves being finished with a row of tiny black and white buttons. Novelties in necklaces also have a charm. Seeds threaded with small beads in between are pretty, also wooden moulds covered with dress material and stitched flat on a matching ribbon makes a change and has a good effect. In the garden a wide range of novel flowers and plants are obtainable. A bird sanctuary can be made for a few pence, and an unusual seat or shelter will bring a touch of novelty to the garden. A screen of living flowers or creepers may be made by planting creepers or flowers in a long box, having handles at each end, and having a trellis for them to creep on. This may be used to hide unsightly spots. In the home many useful novelties may be made by clever fingers. Fireside seats can be made for little cost, using any old material for filling, and with a pretty cover one has a useful seat. A novel idea to store hatboxes in the bedroom is to have a stand or table made with two or three shelves. Have an inner ledge to which is attached a ruched or plain curtain, with the side of the curtain made so that it can be easily unfastened. The top can be polished or covered and used as a table or stand. Novel dishes, trays, flower bowls, also brooches, may be made from plaster of paris. Mix plaster of paris with water, have a mould ready, and pour in smooth. If a brooch is being made put a small gilt safety pin in the back before the plaster sets, let dry, then slip out and decorate or paint with watercolors. Varnish with a clear varnish. A pretty sugar basin may be made from a cocoanut shell. Scrape smooth, sandpaper and polish, and mount on piece of polished wood. A novel brassiere is made from two fancy handkerchiefs. They will also make a nightdress top. Easter egg novelties may be made from blown eggshells decorated with sealing wax. A large bowl filled with honesty with red lacquered stems makes a novel decoration. A belt novelty can be made from an old felt hat. Cut the hat in small pieces the required shape and buttonhole together until you have the desired length; slip into buckle and fasten. A novel filling for sandwiches: take equal quantities of carrots, salted peanuts, cream or butter, mince and mix with a little pepper."

KEEPING AND CURING OF MEAT THROUGHOUT THE YEAR.—Paper prepared by Mrs. A. M. Lawrie:—"During the winter this presents little difficulty, but in hot, sultry weather

constant care is necessary. Mutton killed on the farm is the problem facing most housewives in the country. I prefer the wet method of corning. For this a cask or a large open-necked earthenware jar is necessary. To make the brine: take approximately $\frac{1}{2}$ lb. salt and a teaspoon saltpetre to every gallon of water. The brine must be strong enough to float an egg. If the meat is inclined to be tough, the addition of 2 tablespoons of sugar to the brine will help considerably to make the meat tender and finer-flavored. Next cut the meat into even-sized pieces; legs of mutton corn much more readily than the shoulders. The loin should always be jointed, and in very severe weather the bones may be taken right out. The meat once put in the brine, should be weighted down, and for the first three days turned over every day. For beef it is always best to take out the bones from brisket and other thick pieces before putting in the brine. If one is only corning a little, and then using it soon after, it is not necessary to change the brine, but should it have to be kept for some time, it is a good plan to make a fresh lot of brine after the first week, not quite so strong, and the meat will keep indefinitely if it is turned over occasionally. There is another method. Simply dry salting. Take the salt, saltpetre, and sugar (well mixed), and rub into the meat, then store away in a box or cask.

PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR SUMMER, 1934.

EGGS FOR HATCHING AND DAY OLD CHICKENS

WHITE LEGHORNS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, £2 per 100.

DAY OLD CHICKENS.—15s. per dozen; £4 per 100.

BLACK MINORCAS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, £2 per 100.

DAY OLD CHICKENS.—15s. per dozen; £4 per 100.

**Free on Rail,
Salisbury.**

DELIVERY.—CHICKS—February and March.
EGGS—January and February.

Intending breeders should recognise the importance of establishing their flocks with only the very best of stock also, pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2ozs., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

This has to be done every other day. This is not so satisfactory as the first method mentioned, and the meat has a tendency to become very dry. With this method meat requires soaking in cold water for two hours before cooking. Another successful method is to take the usual brine and add 2 tablespoons of pepper and 1 cup of brown sugar. Bring to the boil, and while boiling drop the meat in and boil for 15 or 20 minutes. Then take off the fire, pack meat into the cask, and pour the brine over; weight it down and allow the fat to set over the top. Do not disturb until it is wanted. The loins of mutton or brisket of beef, if the bones have been taken out, are very nice spiced, for a change, and to do this take out of the brine and wash them. Have ready this mixture:—½ lb. brown sugar, 1 teaspoon allspice, and 1 teaspoon pepper. Rub well into the loin, roll up, and leave for 2 hours before cooking; then cook in the usual way." (Secretary, Miss T. Franks.)

PENOLA (Average annual rainfall, 26.06in.).

July 5th.—Attendance, 21.

HONEY AND ITS USES.—Mrs. W. Clifford read the following paper:—"Honey is the nectar of flowers modified and changed by the honey bee, and has a delicate flavor and aroma imparted by the flowers that is absent from and cannot be given to an artificially made syrup. It varies in color from water white to dark brown—almost black. In some cases it is red and in others of a greenish tinge without any artificial coloring, accounted for by the bees food. In cold weather honey is usually crystallised. Many people prefer it in this state for eating, but if a liquid state is preferred, the jar containing it should be stood in water of about 150deg. to 160deg. Fahr. It is the only food which does not spoil. It will keep for ever. The following are some of the reasons why we should use more honey. By doing so we are helping the primary producers. South Australia produced in 1931-1932: Honey, 1,240,525lbs., valued £18,091; wax, 17,253lbs., value £917; exported honey, 1,058,257lbs.; valued £15,885. The Naracoorte district during a normal year produces about 20,000 tins of honey, which is usually worth about £1 per tin. Honey has a very high dietetic value. It contains iron and potassium for the blood which are not found in cane sugar. It generates energy and is much more easily digested than sugar, containing as it does 75 per cent. of invert sugar, which can be readily assimilated by the body without change, therefore without taxing the digestive organs. In addition there are a number of minor inorganic elements in honey which make it a very valuable food. Dr. Philpots, President of the Food Education Society of Victoria, strongly advises the use of honey in the diet as a preventive of dental decay and as a general assistance to health. If given freely to children it will help to assuage their craving for bought sweets, which in some instances are really injurious on account of the coloring matter used in manufacture, and an excess of refined sugar is now looked on by scientists as a calcium thief, depriving the teeth of calcium salts and ruining them. Honey has a certain percentage of natural calcium and other salts which we need to be healthy. According to Dr. William Tibbles one of the causes of indigestion is excess of sugar. A solution of cane sugar causes heartburn, flatulence, and other gastric troubles, whereas no ill-results follow a solution of invert sugar such as honey. My thanks are due to the secretary of the Victorian Apiarists Association who supplied much of the information and facts contained in this paper. Some ideas and recipes for the use of honey:—Use it instead of sugar in porridge; serve with hot scones, waffles, &c.; cakes made with honey instead of sugar, or with equal quantities of each, keep moist and fresh for a longer period than if only sugar is used; use candied honey in sandwiches for children's school lunches; a paste of honey and soda spread on burns and covered with clean linen quickly relieves pain; mix 1oz. castor oil and 4ozs. honey: take 1 tablespoon night and morning to relieve asthma. Honey can be used in many ways in cough mixtures and a relief for sore throat, bronchitis, and croup. It is a valuable ingredient in cosmetics and toilet soap, and the following recipe is excellent for chapped hands:—White of an egg, 1oz. honey, 1 teaspoon glycerine, sufficient barley flour to make a paste."

RECIPES (supplied by the writer and other members).—*Honey Jumbles*.—1 cup each sugar and honey, ½ packet mixed spice, pinch salt, 1 teaspoon carbonate soda, 4 cups S.R. flour, 2 eggs. Method—Mix honey and sugar well together, then add beaten eggs. After beating lightly, add flour, soda, spice, and salt, which have been previously sifted with flour. Roll out thinly, cut into desired shape, and bake 10 minutes in quick oven. *Wholemeal and Honey Loaf*.—2 cups wholemeal, 2 teaspoons baking powder, 1 pinch salt, 1 cup milk, 1 tablespoon honey. Put honey in cup and add a little hot water, fill up with milk. Pour into a coffee tin and bake about 1 hour with the lid on. *Honey Soap*.—Put 2lbs. yellow soap—cut in thin slices—into a saucepan with sufficient water to prevent it from burning. When soap has dissolved add 1lb. honey and stir until the whole begins to boil. Remove from fire, add a few drops of essence of cinnamon (or any other preferred). Pour into deep dish to cool, then cut in squares. Do not use until it has

hardened. *Honey Sandwich*.—2ozs. butter, 1 teacup sugar, 2 eggs, $\frac{1}{2}$ teacup honey, $\frac{1}{2}$ lb. plain flour, 1 teaspoon cinnamon, 1 teaspoon carbonate of soda, 3 tablespoons milk. Cream butter and sugar well together, add eggs one by one, then honey and sifted flour, soda and cinnamon, and lastly milk. Bake in two sandwich tins 15 minutes. *A Cure for Bouts*.—2ozs. each camomile flowers, sulphur, Epsom salts, $\frac{1}{2}$ lb. honey. Boil together in a quart of water until reduced to about 1pt. Take 1 wineglass every morning before breakfast. *Honey and Lemon Rusks*.—Sieve $\frac{1}{2}$ lb. flour with a pinch of salt, 1 teaspoon cream of tartar, $\frac{1}{2}$ teaspoon carbonate of soda. Beat to a cream 4ozs. castor sugar, 4ozs. butter; beat in 1 egg; add a dessertspoon honey, and beat well. Gradually stir in flour, &c. Add the grated rind of one lemon and mix well. Turn on to board and roll out to about $\frac{1}{2}$ in. thick. Cut into squared fingers and bake until golden brown (about 15 minutes). *Honey Drop Cakes*.—Heat $\frac{1}{2}$ cup honey and $\frac{1}{2}$ cup butter until the butter melts. When warm add $\frac{1}{2}$ teaspoon cinnamon, $\frac{1}{2}$ teaspoon essence cloves. When cold add $1\frac{1}{2}$ cups of flour, 1 egg well beaten, $\frac{1}{2}$ teaspoon carbonate of soda dissolved in 2 tablespoons water, and 1 cup raisins cut finely. Add enough flour to make a dough that will hold its shape. Drop spoonful on greased slide; bake in moderate oven. *Oat Honey Cookies*.—To make oat cookies take 4ozs. rolled oats, 6ozs. flour, $\frac{1}{2}$ teaspoon carbonate of soda, $\frac{1}{2}$ teaspoon each of ground cinnamon, ground cloves, nutmeg, salt, 4ozs. raisins, 1 teacup honey, 3ozs. butter (melted), and one egg. Sift the flour with salt, soda, and spices. Add rolled oats and raisins then honey and melted butter. Mix well so that the last two ingredients may be well worked in. Add egg well beaten, stir for 5 minutes. Drop small portion on a cold oven slide. Bake in moderate oven 15 minutes. *Honey Candy*.—1 cup each honey, sugar, and water, 3 dessertspoons powdered gelatine. Put water and all ingredients in a saucepan and boil $\frac{1}{2}$ of an hour, then pour into dishes which have been dipped in cold water; when set cut in squares and roll in icing sugar. *Honey Date Pudding*.—1 cup S.R. flour, 3 dessertspoons clarified dripping, 1 cup chopped dates, 1 egg, 2 tablespoons honey; rub dripping into flour, add dates. Beat egg yolk and white separately. Warm honey slightly, add yolk, and add to flour, &c. Fold in egg white pour into buttered pudding basin, and steam 3 hours. Serve with honey sauce: Into $\frac{1}{2}$ cup warm honey beat the juice of $\frac{1}{2}$ a lemon or the juice of 1 orange. *Honey Spice Biscuits*.—5 cups of flour, 5 eggs, $\frac{1}{2}$ lb. honey, $\frac{1}{2}$ lb. sugar, 2 teaspoons each baking soda, mixed spice. Boil honey and sugar together, allow to cool, then add well beaten eggs and other ingredients; mix well, and stand overnight. Roll out $\frac{1}{2}$ in. thick, cut into shapes, and bake in moderate oven 10 to 15 minutes. *Honeycomb Toffee*.—4 tablespoons sugar, 2 tablespoons honey, 1 teaspoon carbonate soda; boil sugar and honey for 7 minutes, then take off fire, add carbonate soda; mix well and pour into well buttered dish. Use large saucepan. This quantity will fill 2 soup plates. *Honey Balls*.—1 cup S.R. flour, 2 tablespoons butter, $\frac{1}{2}$ cup cornflour, $\frac{1}{2}$ cup cocoanut, 2 teaspoons honey, $\frac{1}{2}$ cup sugar, 2 eggs. Beat butter and sugar, then honey and eggs. Then flour, cornflour, and cocoanut. Put in teaspoons on greased slide, bake in moderate oven. *Golden Syrup*.—Put 5lbs. sugar in a quart of water in a saucepan, stir well till all is dissolved, then add 2lbs. strained honey in the syrup. Stir well and put in jar. *Buttermilk Cake*.—2 scant cups sugar, 1 cup butter, 2 cups buttermilk, 2 tablespoons honey, 2 eggs, 4 cups plain flour, 2 teaspoons carbonate soda in the milk, fruit. *Honey Sauce*.—Boil $\frac{1}{2}$ pt. water, stir in heaped dessertspoon moistened cornflour, add 2 tablespoons honey, squeeze of lemon juice, 1 teaspoon butter; cook for 3 minutes, stirring all the time. *Honey and Rice Delight*.—1 $\frac{1}{2}$ cups rice, $\frac{1}{2}$ cup honey, $\frac{1}{2}$ cup raisins, 1 tablespoon each butter and lemon juice, cinnamon and chopped almonds. Boil rice until tender in salted water and drain. Brown honey slightly in fryingpan, add lemon juice, raisins, and honey, and pour over rice in shallow piedish. Dab with bits of butter and bake in moderate oven till golden brown; sprinkle with cinnamon and chopped nuts. (Secretary, Mrs. Edith Kidman.)

RENDELSHAM.

July 5th.—Attendance, 12.

RECIPES AND USES OF CITRUS FRUITS.—Mrs. H. Sly read the following paper:—“Lemons and oranges can be used in many different ways. The use of lemon juice in place of vinegar on fish, tomatoes, beet, &c., is a valuable digestive acid. Stale vegetables can be freshened by adding lemon juice to water in which they are soaked. Orange or lemon peel for flavorings should be peeled thinly, and is best grated and rubbed in sugar to bring out the flavor. Lemons for storing should be cut from the tree, leaving a little of the stem on, carefully greased with good dripping, wrapped in soft paper, and kept in a cool dry place. Another method is to pack in dry sand. When lemons are very hard place them in a warm oven before putting on the lemon squeezer. A good remedy for a dry throat or tickling cough: Mix equal parts glycerine and lemon juice, or equal parts honey and lemon juice. Lemon and salt will remove ink stains or rust marks from linen. It is also good for cleaning copper and brassware. Use a cut lemon dipped in salt, afterwards wash in warm soapy water and polish. A few drops of

lemon juice will keep the teeth white. It is also good for shoe polish; a few drops rubbed briskly on black or tan shoes imparts a brilliant polish. Taken in hot coffee, it will often relieve a headache. A teaspoon of mixed spice in hot lemon will often break up a cold, but should only be taken on going to bed, as it causes excessive perspiration. Lemon and orange peel dried and ground into powder is a good flavoring for biscuits, puddings, and cake. When rinsing white silk add lemon juice to prevent it turning yellow. Stains on hands can be removed by rubbing with lemon. A few drops added to prunes when cooking improves the flavor. *Lemon Jam*.—To every pint of water add 1lb. sugar, 1 large lemon shredded finely or put through a mincer. Put the water on the fruit and stand all night. Then boil 1 hour, add sugar and boil again quickly 15 to 20 minutes. (Orange can be used same way.) *Lemon Jam No. 2*.—2lb. lemons, 6 pints water, 12lbs. sugar. Cut lemons very fine, removing all seeds, add water and stand 24 hours. Boil 1 hour or more until peel is soft. Add sugar and boil quickly $\frac{1}{2}$ hour; cool a little before bottling. *Lemon and Orange Marmalade*.—6 large lemons, 2 large oranges sliced thinly; soak in 3 quarts of water for 24 hours; boil 1 hour, then add 6½lbs. sugar and boil briskly 1 hour or more. *Lemon Cheese*.—½lb. butter, 1doz. eggs, 1½lbs. sugar, 6 large lemons (smaller quantity), 2½ozs. butter, 4 eggs, 10ozs. sugar, 2 lemons. Beat eggs, add butter and sugar and grated rind of lemons; strain in the juice of lemons; put in double saucepan and stir over fire until it thickens. Let cool and bottle for use. When cold seal down; it will keep a long time. *Butter Filling with Lemon or Orange*.—3½ozs. butter without salt, 4ozs. icing sugar, and add rind of 1 lemon (or orange grated finely). *Lemon Syrup*.—3 lemons, 2ozs. citric acid, 2lbs. sugar, and 1pt. boiling water. Peel lemons thinly, put all ingredients in a basin, straining in juice of lemons; stir occasionally until sugar and acid are dissolved; 1 tablespoon added to a glass of water. *Lemon Juice*.—1qt. water, 3doz. small lemons, 2½lbs. sugar, rind of 3 lemons. Boil sugar and water until dissolved, add juice and lemon rind peeled very thinly, and boil for 10 minutes; strain and bottle. Enamel saucepan should be used. *Fruit Lemonade*.—Juice of 1 lemon, sugar to taste, a few strawberries or raspberries; crush fruit well, add lemon juice and sugar, and strain into a tumbler of water. *Candied Lemon or Orange Peel*.—Soak peel in salted water for 3 or 4 days, drain, and bring to a boil until soft, in clear water. Then make a syrup of 2 cups of sugar and 1 cup water, boil 8 or 10 minutes, and put the peel, which has been well drained, into a basin and pour syrup over it. Stand 5 days, then drain off syrup and boil 20 minutes. Put peel into syrup and boil slowly until clear. Remove and drain well; dry slowly and put away in jars. *Orange Marmalade* (common oranges).—4lbs. oranges cut in halves, remove cores and pips, slice fruit finely, add 16 cups water; stand overnight and boil 1 hour, then add 12lbs. sugar and boil quickly another hour. *Orange Conserve* (from Navel oranges).—Slice up finely the Navel oranges. To each 1lb. fruit add 1pt. water, boil until soft, then measure cup for cup of fruit and sugar; add the juice of 2 lemons to every 3lbs. of fruit, boil $\frac{1}{2}$ hour. *Orange Marmalade*.—Slice 12 oranges, 2 lemons; add 10 pints water; stand 24 hours, then boil for 1½ hours; add 12lbs. sugar and boil 1½ hours longer or until it jellies. The lemons can be cut in quarters if liked, and removed when marmalade is cooked. *Orange Jelly*.—10 large oranges, 2 or 3 lemons; slice fruit, allowing ½pt. of water to each fruit. Boil slowly until fruit is soft, strain through jelly bag, then measure cup for cup of liquor and sugar. Boil again quickly until it jellies. Bottle and allow to cool before covering. *Orange Cake*.—1½ cups flour, ½ cup butter, ½ cup sugar, 3 eggs, ½ cup milk, 1 teaspoon cream tartar, ½ teaspoon soda, grated rind 1 orange. Cream sugar and butter, add eggs, then milk, flour, and orange peel. Beat well and bake in sandwich tin 20 minutes in moderate oven. Mix icing sugar with orange juice and ice when cold. *Orange Biscuits*.—7ozs. butter, 5ozs. sugar, 5ozs. golden syrup, 8ozs. flour, 4ozs. cornflour, ½ teaspoon spice, 2ozs. each cocoanut and chopped walnuts and finely chopped orange peel. Cream butter and sugar, add golden syrup and grated or chopped orange rind, and then the other ingredients. Knead well and let stand a few hours or all night, in a covered dish, roll out $\frac{1}{4}$ in. thick, cut in shapes, and bake in a moderate oven 15 minutes." (Secretary, Mrs. G. Andrews.)

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Fat Lamb and Export Pork Industries.

The Minister of Agriculture (Hon. A. P. Blesing) has received the following report on the Fat Lamb and Export Pork industries from the Deputy Director of Agriculture (Mr. W. J. Spafford) after he had made some investigations into the matter whilst on a visit to Victoria during the recent Melbourne Royal Show.

FAT LAMBS.

After closely following the judging of the mutton breeds of sheep at the Show, discussing the matter of types and methods of handling with many Victorian breeders, and visiting saleyards and slaughterhouses, I could only come to the conclusion that in the matter of breeding and handling of lambs on farms South Australian farmers are working on correct lines.

EXPORTS OF LAMB CARCASSES FROM VICTORIA.

The number of carcasses of lamb exported from Victoria is more than 10 times the number sent from South Australia, and despite the fact that the quality of our lambs is at least equal to those of Victoria the prices received for our neighbor's lambs are greater than what we receive, and this appears to be due to the large numbers produced. For each of the past five years Victoria has sent overseas considerably more than 1,000,000 lamb carcasses, the actual figures being:—

	Carcasses.
1928-29	1,168,358
1929-30	1,515,116
1930-31	1,406,565
1931-32	1,615,736
1932-33	2,424,848

TYPE OF EXPORT LAMBS PRODUCED IN VICTORIA.

The numbers of sheep of the various mutton breeds exhibited at the Melbourne Show give some indication of the popularity of the breeds, although it is necessary to visit sales throughout the season to arrive at a correct idea of the proportion of the different crosses being slaughtered for export.

The animals entered for competition in the various sheep classes at the 1933 Melbourne Show, not including lambs at foot, were as follows:—

Border Leicester	200
Southdown	171
Corriedales	127
Dorset Horn	114
Lincoln	99
Shropshire	62
English Leicester	50
Ryeland	48
Romney Marsh	38
Polwarths	20
Suffolk	16

At the time of the Melbourne Show the lambs submitted for sale in the saleyards were predominantly crossbreds containing much Border Leicester blood, and of a yarding of over 78,000 lambs at Newmarket on September 26th, 1933, it was estimated that more than 75 per cent. of the lambs were sired by Border Leicesters. On the other hand, the lambs by Southdown and Ryeland rams were only just approaching maturity, and would not be submitted for sale until a little later on. In conversation

with interested parties, I gathered that the lambs exported from Victoria are predominantly of two types—(a) the long-bodied, white-fatted lambs by Border Leicester, and (b) the Down type of lambs sired by Southdowns and Ryeland, with the latter breed becoming increasingly popular.

The relatively high prices secured for Victorian lambs appear to be due to the continuity of supplies of large numbers of lambs of similar type, and if we can increase our production of carcasses and keep to the type we are now raising there seems to be no reason why we should not secure prices equal to those paid for Victorian lambs.

PIGS FOR EXPORT.

Victoria is only just becoming an important exporter of pig products, and as we have just arrived at the stage of commencing to ship pig carcasses overseas, it is of the utmost importance that South Australia closely follows all the developments in this direction.

The first thing of importance to note is that there has been a reversal of the type of trade being undertaken by Victoria, for in the past five years the attempt to export bacon and hams overseas has been almost discontinued, whilst rapid strides have been made in the export of frozen pork. These facts are clearly seen in the next table:—

Exports of Pig Products from Victoria.

	Frozen Pork.	Bacon and Hams.
	Lbs.	Lbs.
1928-29	5,130	153,362
1929-30	14,017	161,070
1930-31	253,419	88,168
1931-32	1,565,668	68,554
1932-33	2,148,500	59,574

The fact that the principal pig product to be exported from Australia must consist of frozen carcasses of a weight suitable for conversion into bacon on arrival in Great Britain is generally recognised in South Australia, but we have not yet realised to the full what is the best type of pig to produce for the purpose.

TYPE OF PIG PRODUCED IN VICTORIA.

Close inspection of the pigs submitted for sale for slaughter during Melbourne Show Week disclosed that the great bulk of the bacon pigs were of the long, deep-bodied, fine-shouldered type demanded by the bacon curers in Great Britain, and most of them were of a white color. A count of the pens of bacon pigs showed that almost exactly 70 per cent. of the animals were by Large White boars, most of the pigs being half-breds, whilst nearly all of the remainder were half-bred Tamworths, there being only very few Berkshires and British Blacks. Amongst the porkers about 50 per cent. showed Mid-York blood, and there was a fair proportion of Berkshires, although Large White and Tamworth-cross pigs were in evidence.

As the Department of Agriculture has for some time been educating pig producers towards raising the ideal bacon pig we feel that it will not be long before our own markets will be well supplied with the pigs of a type to bring maximum prices, and as a matter of fact great improvement in this direction has been noticeable in the past few months.

RECOMMENDATIONS.

1. It is necessary for an increased production of fat lambs suitable for export in South Australia if we are to get maximum prices.

2. In encouraging greater production of fat lambs we should stick as closely as possible to the Down type of lamb, which we have conclusively proved can be raised successfully in our conditions.

3. Considering that the quality of South Australian lambs is at least as good as that of the other States, and our prices a bit lower, we would secure an advantage if all lamb carcasses exported from Australia carried one brand rather than that of a particular State.

4. Every encouragement should be given to the production of pigs suitable for export so that exporters can operate freely in our markets. As in all of the principal pig-exporting countries of the world, the use of Large White boars will do more than anything else towards the production of the desired type of animal.

5. A quick change in the type produced and the rapid extension of our export trade would probably help more than anything else to overcome the ill-effects of a stored surplus of wheat if the recent wheat agreement leaves us with an unexportable surplus. With free propaganda we could persuade pig raisers to feed wheat to pigs and sell it as pork, rather than suffer the damage that must follow the holding up of unsaleable wheat.

Urrbrae Agricultural High School.

A day school for agricultural students has been opened at Urrbrae. A course similar to that of other Agricultural High Schools has been provided and a staff of experts appointed. The school was opened in February, 1932, with first year, intermediate, and leaving classes.

All students who have passed the Qualifying Certificate Examination or have spent a year or more at a secondary school are eligible for enrolment, provided:—

- (a) That they intend to become primary producers; or
- (b) That they wish to take a University course in agriculture, with the object of becoming research workers or teachers of agriculture.

A general education is provided, and students may sit for Intermediate and Leaving Examinations. The following are the subjects studied:—English Literature, Algebra, Geometry, Arithmetic, Chemistry, Botany, and Agriculture. (Latin to Intermediate standard if required for Matriculation to Agricultural Degree course.) *Agriculture*, both in theory and in practice, receives special attention. The study of *Farm Crops* and *Animal Husbandry*, together with *Farm Shop work* or *Farm Mechanics* comprises an important part of the school's activities.

The number of admissions for 1934 will be limited. Early application for admission should be made on the prescribed form, which is obtainable from the Education Office.

On application to the Head Master, efforts will be made to obtain suitable boarding accommodation in the neighborhood for those students requiring it.

Control of Sorrel.

Reply to the Secretary of the Marama Agricultural Bureau, who asked, "What is the best method of ridding land of sorrel?" Mr. W. J. Spafford (Deputy Director of Agriculture) says:—There are no materials that can be added economically to soils in the low rainfall parts of this State to rid them of sorrel. In the wetter portions of the country, where valuable crops are grown, the addition of sufficient lime to alter the reaction from acid to neutral leads to the control of the weed, but this treatment is not warranted for ordinary cereal-growing conditions.

After a few years of cropping, with the constant cultivation of the land which is necessary, sorrel should disappear from the fields at Marama, as the aeration and exposure should soon overcome the acidity of the surface soil which is encouraging the sorrel to spread.

Citrus Trees Shedding their Leaves.

Reporting that both orange and lemon trees in the Narridy District were shedding their leaves, the Secretary of the Local Branch of the Agricultural Bureau has been advised by the Chief Horticultural Instructor (Mr. G. Quinn) that it is quite a natural procedure for citrus trees to cast their leaves annually, but usually this is done gradually, and the effect is not to leave the tree totally bare of foliage at any one period, such as is the case with truly deciduous kinds of fruit trees. Apart from an attack of some specific pest or disease, when an orange or lemon tree sheds nearly all of its leaves simultaneously the cause generally can be attributed to some ineffective root action.

**Mobiloil
for Me!**

says the TRACTOR OPERATOR
**"...because I can depend on it for
long, hard work"**

**You want your tractor to work at its
best right through the harvesting.
Use Mobiloil.**

No matter how hard or how continuous the work, Mobiloil will stand up, and enable your tractor to stand up, too.

Mobiloil keeps its body longer; and it enables you to get the most power and 'acreage' from your fuel. It's a money-saving lubricant!

The most **DEPENDABLE** tractor fuel you can buy is **VOCO**. It, too, will stand up to the hardest work.

The ideal partner for Mobiloil is—
**VOCO POWER
KEROSENE**

Mobiloil

Mobiloil "C" for Gears . . . Mobilgrease for Chassis Lubrication

VACUUM OIL COMPANY PTY. LTD.

This may be due to excessive wetness in the soil about the roots during the winter season, or to too great a deficiency of moisture in the land during the period of summer. Again, exposure to cold, cutting winds will frequently defoliate these trees, though that is usually noticed more on the side facing the prevailing wind in the locality.

A lack of nutriment in the soil occupied by the roots may hasten the fall of leaves; and intensely cold soil, but not necessarily actual frost formation on ground or plants, will also, if prolonged, cause leaf shedding. These points are presented for your consideration, as without a personal knowledge of all or such of these predisposing influences as may be or have been present in the locality, I am quite unable to definitely state which are the operating factors.

Improvement of Pastures.

The South Australian Committee of the Australian Dairy Council desires to institute a series of pasture improvement demonstration trials on the properties of private dairy farmers in South Australia.

The demonstration area will be planted with a mixture of pasture varieties considered most suitable to the conditions offering, and the results obtained will serve as an illustration of the importance of pasture improvement, not only on the carrying capacity of the land, but also on the health of livestock grazing thereon.

In this connection the Committee is prepared to supply seed and manure to selected trialists, and co operate with them in the planting and management of the demonstration fields.

Landholders who propose seeding pasture areas in the coming year are invited to communicate with the Secretary of the Committee, L. S. Smith, Office of Minister of Agriculture, Adelaide, with a view to obtaining free supplies of seed and fertiliser for planting such land. Those assisted in this direction will be expected to forward monthly reports showing the development of the varieties seeded and, as far as possible, supply a comparison of the amount of produce obtained from such fields relatively to that secured from other paddocks receiving different treatment.

It is hoped to establish demonstration trials in various districts throughout the State, and at the end of each season publish a review of the reports received. In this way valuable information regarding the establishment of pastures for various localities will be made available. Applications should be forwarded on or before January 1st, 1934, and contain the following particulars:—District, area of field to be planted, pasture varieties suggested, area of farm, class of land, number of cows kept, manure.

The various trials will be conducted under the supervision of the South Australian Committee of the Australian Dairy Council, who from time to time will issue reports on the results obtained.

VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers, Stock and Brands Department.]

Agricultural Bureau, Brentwood, reports cow whose nose appears to be blocked as though with catarrh.

Reply—Give the cow 1 tablespoon Stockholm tar smeared on the tongue once daily for a few days. Provided the condition is not chronic it should clear up as warmer weather comes on. It is not a common condition in cows, and should not occur.

Agricultural Bureau, Brentwood, reports cow and calf stiff in all legs.

Reply—The stock appear to be suffering from an insufficiency of minerals (lime and phosphorus) in the diet. Supplement the grazing by handfeeding some bran and crushed oats, or a little linseed meal, with some chaff. Damp the feed, and mix in it daily a handful of superphosphate, or for preference a heaped tablespoonful of

Heres a **QUALITY TYRE** *at* **ECONOMY PRICES**

Here's the perfect combination of long-lasting quality and economy. Flexifort—the tyre that is built with generous strength from casing to tread—is available at greatly reduced prices. Not only in first cost, but in long mileage and trouble-free service does Flexifort mean greater economy. See your local dealer—he carries stocks of all popular sizes of this low priced quality tyre.

The Low Priced Quality Tyre

dicalcic phosphate; whichever of these mineral supplement is used, it should be introduced gradually, giving a small amount to begin with and gradually working up to the full amount as the stock become accustomed to taking it. A daily allowance of salt, 1oz. to 2ozs. should also be given. As an alternative to giving the mineral supplement mixed in with box feed, they can be mixed with an equal quantity of salt to make a lick which can be put out in a box—sheltered from weather—in some convenient place where the stock could have access to it to lick it at will. It would be a sound procedure to feed these mineral supplements regularly to all cattle.

Sevenhills asks for a lick for sheep grazing on improved pastures.

Reply—The following lick is suggested:—Dicalcic phosphate (37 per cent., approximately, P_2O_5), 40 parts; salt, 60 parts. It not taken readily by the sheep, a little crushed oats could be added. The price of dicalcic phosphate (37 per cent. P_2O_5) is about 17s. 6d. per cwt. for small lots. The feeding of licks should start from the time the grass begins to seed, and should be continued throughout the dry period of the year.

Angorichina Hostel asks how to dehorn a 10 months old bull.

Reply—The only way to do this is to cut off the horns, which can be done with a meat saw or with a sharp, broad chisel. Cut off level with the skull. Sear the arteries, and swab daily with following lotion:—Creosote, ½oz.; oil of turpentine, 3ozs.; olive oil, 10qzs. Throw the bull to do the operation.

Taplan Conference: "Does mammitis recur in a cow?"

Reply—Mammitis is due to invasion of the udder tissue by certain germs. This invasion may lead to a mild or severe attack of inflammation of the udder. Again, the disease may become chronic with definite udder changes, or apparent recovery may take place. In the latter case and even in old chronic cases, a flaring up of the disease may take place and an acute mammitis again occurs. The only way in which it is possible to say whether a cow has mammitis or not is by a bacteriological examination of the milk from each of the quarters of the udder. Cows with apparently healthy udders can have the germs which cause mammitis present in the milk. Under suitable conditions and especially after calving, the disease becomes active.

Taplan Conference: "Is it advisable to dispose of a cow that has had mammitis?"

Reply—This depends on the circumstances of each case, and advice should be sought from the Stock and Brands Department before such a course is adopted. The following points should be considered before disposing of a cow:—(1) Mammitis is extremely common and few herds are free from it. (2) If the policy of disposal is adopted, then all the cases of mammitis will have to be removed from the herd. Again, only a bacteriological test of the milk of all the cows in the herd will show what cows are affected and what ones are not. (3) The disposal of a number of cases of the disease may mean that the dairyman has to purchase cows outside. The "bought" cow frequently introduces the disease. (4) The extent of the disease in the herd. If only one case has occurred it may pay to dispose of it. (5) Again, the numbers of quarters affected are of importance. A three-quarter cow may pay her way, whilst a cow with two or quarters affected will probably not do so. (6) The type, condition, and age of the cow should be considered.

Taplan Conference: "Should a cow be allowed unlimited supplies of water after calving?"

Reply—Yes. Cows require a good supply of water at all times. They should be allowed to take as much as they want.

Taplan Conference: "What is a good lick for cows?"

Reply—The following is suggested:—Dicalcic phosphate (37-38 per cent. P_2O_5), 60 parts; salt, 50 parts. For a 2gall. cow on good chaff, give 6ozs. of the above lick mixed in feed daily. For bigger producers increase the amount of lick by 2ozs. of lick for each gallon of milk. Superphosphate is not advised.

Taplan Conference: "What is the cause of gastro-enteritis in lambs and its treatment?"

Reply—The symptoms shown should have been stated. Gastro-enteritis (inflammation of the stomach and bowels) is invariably accompanied by "black scours." It may be "parasitic" in origin or if the lambs are in "high condition," it may be a symptom of infectious entero-toxaemia. It is suggested that particulars of the disease be sent to the Stock and Brands Department, and, if possible, a typically sick lamb be brought down for *post mortem* examination.

Taplan Conference: "Cure for strangles."

Reply—Strangles is a contagious disease of the horse and is chiefly spread by the contact of an affected horse with a healthy one. The disease has been very prevalent in the State during the past year, and in those cases which have come under notice the history is that a horse has been purchased (usually at a horse sale) a short time before the outbreak of the disease. *Prevention*—(1) Isolate any newly bought horses for two or three weeks. (2) Do not buy any horses showing a nasal discharge or swelling between the lower jaws. (It is also advisable to make your purchases well before harvest operations, as an outbreak of strangles can disorganise the farm teams). (3) There is preventive vaccination, but its use is not advised for farm teams. (4) Isolate any horse showing signs of a cold or swelling under jaw and seek veterinary advice. *Cure*—The disease takes its course. Isolate, put out of work, keep warm, and give nourishing but light feed. Steaming of the nose is advisable. The swelling under the jaw should be fomented and lanced when ripe. Strangles vaccine is very useful in an outbreak of the disease. Advice should be sought as to how to use it.

Taplan Conference: "What is the cause and cure of 'mud fever'?"

Reply—This is an inflammation of the skin of legs, heels, and coronets of horses' feet when these parts are subjected to long-continued irritation. The skin surface becomes reddened and slightly swollen and area is painful to touch. It may be itchy and the horse may rub and bite it. Treatment consists in clipping hair off affected area and washing with warm soap solution. Then apply following lotion twice daily:—Lead acetate, loz.; zinc sulphate, 6 drams; water, 1 pint. Shake thoroughly before applying.

Taplan Conference: "Is it an advantage to clip horses?"

Reply—Yes. They "dry out" quickly and do not lose condition so easily. Sore shoulders are not so common, mainly because loss of condition does not occur. They are not so subject to lice and are easily kept clean.

FRIENDLY SERVICE ALL THE TIME.

Some of the time, if not all the time, you must save money, but if you are Mr. Average Citizen you know that ALL the time is nearer the mark.

Whatever your margin on any one week's salary, it won't provide for a sudden necessity to pay, say, £50 or £100. No one week's salary will provide education for your children, heavy medical expenses, or comfort in your declining years.

Therefore, to make provision for the big calls, you HAVE to save, more or less, ALL the time. The Commonwealth Savings Bank provides a friendly efficient savings service—ALL the time.

Commonwealth Savings Bank of Australia

GUARANTEED BY THE COMMONWEALTH GOVERNMENT.

THE VIABILITY OF SEEDS.

[*The Bulletin of Miscellaneous Information* (No. 6, 1933) issued by the Royal Botanic Gardens, Kew, contains an article by MR. J. H. TURNER on the *Viability of Seeds*, extracts of which are published below. Throughout the original the names of authorities are acknowledged for statements concerning the various cases mentioned.]

Little was known about the vitality of seeds of wild plants until De Candolle, in 1832, observed that "certain portions of soil, which, by reason of terracing work, were exposed to the air after several centuries, covered themselves the first year with a multitude of individuals belonging to certain species, sometimes uncommon in the vicinity." He concluded that the seeds of these species had remained viable for considerable periods in the soil.

Although much has been written regarding this subject since the time of De Candolle, the literature is very scattered, and with few exceptions the accounts are based upon observations rather than experiments.

Duvel has shown that the average life of seeds, as of plants, varies greatly with the different families, genera, and species, but there is no relation between the longevity of plants and the viable period of the seeds they bear. Some seeds retain their power of germination for a few days only, such as the willows and poplars; others remain viable for months or even a considerable number of years. The life period of any species of seed, provided that it has been thoroughly matured, is largely dependent on environment. Climatic influences play an important part, and loss of vitality is especially marked in the case of seeds stored in places of high temperature and humidity.

BURIED SEED.

Only a limited number of cultivated plants produce seeds which retain their vitality for any length of time when buried in the soil, but the seeds of many plants known as "weeds" are capable of living in the soil for extended periods. Duvel found that seeds of the cultivated sunflower, when buried for a year at three different depths, all decayed, whilst those of the wild sunflower retained their vitality, and gave a germination of 66 per cent. at the maximum depth of 3ft. Many seeds are better preserved the deeper they are buried. At 3ft. below the surface, the amount of moisture is always more uniform, the supply of oxygen is greatly lowered, and the temperature is much reduced. The majority of seeds germinate best when subjected to daily alterations in temperature, and as these alterations do not take place at a depth of 3ft. below the surface there is a better preservation of vitality as a result of the more dormant condition of the seed.

It is well known that on the soil of old pastures and woodlands freshly turned up, or on the mud of drained ponds, plants previously unknown in that locality appear. Some of these may have risen from seeds recently transported, but others must have grown from seeds which have lain dormant in the soil for frequently a very lengthy period. A striking illustration of this was afforded during the War by the countless plants that appeared in devastated areas. The upheaval of the ground by continuous shelling brought innumerable dormant weed seeds to the surface, where they germinated, and so completely covered the ground that all appeared to be a level plain.

Hill, in the "Flora of the Somme Battlefield," says: "In July poppies (*Papaver Rhoeas* L.) predominated, and the sheet of color as far as the eye could see was superb; a blaze of scarlet unbroken by tree or hedgerow. Here and there long stretches of chamomile (*Matricaria Chamomilla* L.) broke into the prevailing

red and monopolised some acres; and large patches of yellow charlock were also conspicuous, but in the general effect no other plants were noticeable, though a closer inspection revealed the presence of most of the common weeds of cultivation . . . Charlock (*Sinapis arvensis* L.) not only occurred in broad patches, but was also fairly uniformly distributed, though masked by the taller poppies. Numerous small patches were, however, conspicuous, and these usually marked the more recently dug graves of men buried where they had fallen . . . No doubt in the ordinary operations of ploughing and tilling of the ground in years before the war much seed was buried which has been brought to the surface by the shelling of the ground and subsequent weathering. In this connection the presence of charlock on the more recently dug graves, where the chalk now forms the actual surface, is of interest, since it adds further proof of the longevity of this seed when well buried in the soil." The appearance of charlock on earth thrown up by shells and in shell craters when there was no trace of it on the undisturbed ground was remarked by other botanists during the War.

Farmers often object to deep ploughing, especially on light soils, as it may "bring up the charlock." A field had been seeded down to grass, and kept as a hay field and pasture. Sixteen years after the elimination of the seed source, a heavily laden wagon was taken across this field after a hard frost and thaw; the wheels sinking deeply tore up the ground, bringing much subsoil to the surface. In the following spring the furrows were filled with charlock, and when they flowered there were two parallel yellow ribbons marking the irregular course taken by the wagon. There was not another charlock to be seen in the field. After being under grass for 24 years, the field produced fumitory, poppies, and charlock in abundance directly the surface was broken and the subsoil exposed to the atmosphere. Otherwise none of these weeds was ever seen.

A field was laid down in grass in 1869, and so remained until 1893, when *Sinapis arvensis* appeared in patches. Other experiments show that seeds of charlock can retain their vitality in the soil for 40 years, and that although the germination of stored seeds of charlock after 10 years was 24 per cent., those which had been buried for the same period gave a germination of 87 per cent.

Professor E. J. Salisbury relates that during the building of his house on former arable land corn field weeds appeared, and notably plants of the blue pimpernel (*Anagallis foemina* Mill.), a plant now exceedingly rare in that locality.

Pugsley mentions that *Fumaria officinalis* appeared on a heap of earth dug from the foundations of a house. Holmes describes how a house that had been standing for about 100 years was pulled down and the ground left vacant for a time. The following year henbane (*Hyoscyamus niger*) grew luxuriantly amongst the soil that had been exposed by clearing the foundations.

There are many instances of the longevity of buried leguminous seeds. *Ulex europaeus* came up when trenches were dug in land which had been cleared of this plant and cultivated for 25 years. New trees were planted 15 years later, and the gorse re-appeared, i.e., after the seeds had been buried for 40 years. In another instance seeds of gorse were brought to the surface after 25 years, and germinated most abundantly where originally the gorse grew strongest. Further, a gorse bush had been removed from a garden for about 20 years, yet every year on stirring the soil new seedlings appeared.

The appearance of broom (*Cytisus scoparius*) in the bare slopes of a road cut through the grassy, park-like land of Wimbledon estate is described. It seems probable that the young plants may have originated from seed that had remained dormant for a century.

Plants of *Trifolium repens* often appear abundantly in land freshly brought under cultivation, and in the Fen districts white clover comes up so quickly after the land has been drained and ploughed that the inhabitants can scarcely be convinced that it is not a spontaneous product of the soil.

Hard seeds of *Acacia* spp. have been found buried deeply in the soil of eucalyptus forests where there was no other acacias within a mile, and under trees of *Acacia dealbata* seeds buried as deeply as 18in. below the surface gave perfect germination.

A rare example of the sudden rush to life of long-buried seeds occurred at Westonbirt where in the winter a quantity of *Rhododendrom ponticum* was cleared away in a wood, and in the following June the ground was literally covered with the scare blossoms of *Campanula patula*, of which the only specimen previously known at Westonbirt was at the edge of a wood nearly a mile away.

Reference was made to experiments with seeds from soil samples taken from forests that had been growing for known periods on formerly cultivated land. Germination of numerous farm seeds was secured, and it was estimated that some of these seeds had been lying in the soil for 100 years.

Probably the record longevity for any seed is that recorded by Olga, who obtained approximately 100 per cent. germination with "seeds" of *Nelumbo nucifera* Gaertn, which he found on a peat bed buried 2ft. deep with loess in the Pulantien River Valley in Southern Manchuria, the bed being 12½ metres above the present water level of the river. Judging by the age of willow trees (*Salix babylonica*) on the bed of this former lake, and from the rate of lowering of the water level, it is probable that the "seeds" are at least 120 years old, and may be 400 years old, or even older, judging by the rate of erosion. Seedlings raised at Kew were potted and planted in the Victoria Regia pool, where they grew vigorously. The embryo of this plant is kept in an ideal state of quiescence by the hard pericarp, and it is this impermeability of the "seed" which no doubt is the chief factor for its prolonged vitality. Peat appears to be an ideal medium for seed preservation, and its antiseptic properties prevent deterioration through fungal attack.

Experiments with buried seeds were made by Beal in the United States, and at intervals of five years, from 1879-1920, and later of 10 years, seeds in the experiments were tested for germination. Results show that, after being buried for 50 years, seeds of *Brassica*, *Oenothera*, *Polygonum*, *Rumex*, and *Verbascum* still germinate.

Other tests of Duvel (United States) under more natural conditions in pots showed that seeds of 51 species buried at depths varying from 6in. to 42in. gave a good germination after being buried for 20 years. On the whole, the most deeply buried seeds retained the vitality the longest.

Seeds submerged in mud and water also have the power of resting until conditions favor germination. It has been shown that the germination of some aquatic seeds can be delayed four or five years without impairing their vitality, and seeds of many land and water plants will germinate after being kept in mud and water for periods of four to seven years.

It is evident that seeds washed down from the higher reaches of a river will germinate after a prolonged submersion in salt water, and that some seeds will withstand the action of salt water for considerable periods.

STORED SEEDS.

There are numerous instances of the germination of stored seeds. In 1850 Robert Brown, out of curiosity, sowed some seeds from a collection in the British Museum. He succeeded in making several of them germinate, particularly a seed of *Nelumbium speciosum*. It was shown that in four separate experiments with *Nelumbium* 85 per cent. of these fruits had retained their power of germination for 150 years.

Seeds of known age from 25 to 135 years, preserved in the Herbarium of the Natural History Museum in Paris, showed that seven species retained their power of germination after 50 years. The oldest seeds found viable were *Cassia bicapsularis* (87 years), *Cytisus biflorus* (84), *Trifolium arvense* (68), *Lens esculenta* (65), *Stachys nepetifolia* (77), *Lavatera Olbia* (64), *Nelumbium luteum* (56). Seeds of other Leguminosae preserved in loosely corked bottles in Museums in the Isle of Wight and Kew germinated at ages as follows:—

<i>Anthyllus vulneraria</i>	90 years, 4.0 per cent.
<i>Trifolium stratum</i>	90 years, 14.1 per cent.
<i>Trifolium pratense</i>	81 years, 2.6 per cent.
<i>Lotus uliginosus</i>	81 years, 9.6 per cent.
<i>Melilotus alba</i>	81 years, 163 seeds, 1 germinated.
<i>Cytisus scoparius</i>	81 years, 636 seeds, 4 germinated.
<i>Medicago orbicularis</i>	78 years, 22.0 per cent.

Seeds of *Polygonaceae*, *Cruciferae*, *Papaveraceae*, and *Scrophulariaceae*, failed to germinate.

Seeds sent from Kew to Melbourne in 1856, and put aside in a dry cupboard and opened in 1906 were tested.

These tests confirmed other experiments, the *Leguminosae* providing more than half the number of cases of longevity. Further tests showed small percentage germinations of *Goodia lotifolia* and *Hovea heterophylla*, both 105 years old. Ewart formed the opinion that however dry the seeds may be they cannot indefinitely prolong their vitality. Even the most resistant seeds after 50 to 100 years show a pronounced decrease in the percentage germination, and the general trend of the curves is such as to show that the probable extreme duration of vitality for any known seed may be set between 150 and 250 years (*Leguminosae*).

Seeds of *Ribes rotundifolium* may lie dormant in the forest floor for protracted periods, and germinate soon after the ground is disturbed through fires, by logging operations, or by the roots of trees blown down by the wind.

Records are quoted of seeds of *Mimosa pudica* from hermetically sealed bottles germinating after 100 years; *Acacia lophanthia*, 68 years; *Pelargonium*, 50 years; and *Roseda odorata*, 45 years.

Some of the instances of supposed seed viability are unsupported by definite evidence, and the "classical case of seed longevity" described by Heldreich was evidently founded on taxonomic errors. Heldreich suggested that the sudden appearance of a supposed new species, which he named *Glaucium Sepieri*, and of *Silene juvenalis* in the Laurion area was due to their seeds having remained dormant for 1,500 to 2,000 years in the soil under the heaps of old mining debris. An investigation by Dr. Turrill has shown that *Silene juvenalis* is conspecific with *S. subconica*, a not uncommon species in the countries around the

Agean Sea. There is nothing in the taxonomy or distribution of the *Silene* and *Glaucium* to make it improbable for them to occur naturally in the Laurion district, and in all probability both species were in the neighborhood before the heaps of debris were removed and simply spread on the vacated and denuded ground in the absence of close competition.

MIRACLE OR MUMMY WHEAT AND MUMMY PEAS.

There is no authenticated evidence that wheat taken from undisturbed Egyptian tombs will germinate. An experiment was made at Kew some 30 years ago with grain from a model granary found in a tomb of the nineteenth dynasty and brought to England by Sir E. A. Wallis Budge. Samples were tested under various conditions, and the effect of colored glass was tried in the effort to induce germination, but after three months the grain had turned to dust. Percival states: "I examined a number (of grains) found by Professor Flinders Price in the Graeco-Roman Cemetery at Hawara (about First Century, B.C.) . . . the embryo had become dark brown, its plumule greatly shrivelled, and little of its structure was visible."

In grain from a tomb of the eighteenth dynasty, 1400 B.C., "all the parts were more brittle, and the embryo more completely disorganised than in the grains from Hawara. It is scarcely necessary to observe that the embryos were dead. Professor Petrie tested samples of grain of Graeco-Roman age which he found at Hawara immediately after exhumation. The grains were sown on the banks of a canal in varying degrees of moisture . . . but none germinated."

According to Gain, although Egyptian wheat and barley often have an exterior appearance of good preservation, the embryo has undergone a marked chemical change, and is no longer viable. This change shows that the dormant life of the grain has been long extinct.

Sir E. A. Wallis Budge has accounted for the popular belief in the germination of grain from Egyptian tombs, and explains that for hundred of years the natives of Egypt have used the halls of tombs for the wheat and barley obtained from Syria. Ancient coffins have been packed in this Syrian wheat and sent to England, and such grains will, of course, grow. During the last 30 years the native dragoman and guides have found that tourists will buy "mummy wheat," and they keep supplies in the tombs, carefully hidden, which they dig up under the eyes of the astonished visitor, and offer as "mummy wheat" or "mummy barley."

Cereals are ill adapted for a prolonged period of quiescence. Sifton has shown that Canadian wheat may retain its vitality for 18 years, and that the longevity of oats is greater than that of wheat, possibly owing to the protection of the hulls. Nineteen-year-old kernels of oats gave a germination of 41 per cent.

Percival records an exceptional case of wheat remaining viable for 25 years.

White found that in Australia the germination of wheat is lost after 11-16 years, and that of barley after 8-10 years.

Fanciful tales are current with regard to "miracle" or "mummy" wheat, *Triticum turgidum* var. *mirabile* Korn and "mummy peas," *Pisum sativum* var. *umbellatum* (Mill.) Ser.

Miracle wheat is the commonest branched form of *Triticum turgidum* met with in South Europe and the North African coast. It is usually cultivated as a curiosity. Fasciated forms of the pea, similar to the so-called mummy pea, are figured by Tabernaemontanus in his *Herbal*, published in 1590, and Miller in his *Gardeners' Dictionary*, eighth edition, 1771, described the form under the name *Pisum umbellatum*, rose or crown pea.

The misleading name "mummy pea" is equally applied to the non-fasciated form, sometimes grown in cottage gardens. It is popularly asserted that miracle wheat and mummy peas originate from Egyptian tombs, and that such seeds germinate when sown, but in every instance the statements prove to be without foundation.

GOVERNMENT EXPERIMENTAL ORCHARDS, BLACKWOOD AND FULLARTON.

[Paper read by R. FOWLER (*Manager, Blackwood Orchard*) at the Annual Meeting of the Fruitgrowers' and Market Gardeners' Association.]

Science is nothing more than systematic observation, and in the study of horticulture there is a very wide field of investigation still open. The scientist in the laboratory by means of water cultures or by growing trees in well washed sand, watered with nutrient solutions, can tell what fertilisers plants require to make, strong, healthy growth, but to be of any practical benefit, those fertilisers need to be tried in the field under natural conditions, and before the results can be considered as conclusive many factors have to be taken into consideration, and it is here that the horticulturist or field worker has to play his part. In attempting to do manurial experiments, for instance, upon apple trees, the results generally have been imperfect and the experimental error enormous, and these results have been due, in a large measure, to the fact that the experimental materials were not standardised, nor were the plots sufficiently replicated to reduce variations due to soil conditions to a minimum. The field experiment should be the inspiration for the more intensive pursuit of detail in the laboratories, and the demonstration plot or extension trial would seem to be essential for translating the general principles elucidated in the field experiment to purely local conditions.

It is not the purpose of this paper to discuss all the phases of the investigation of a horticultural problem, but rather to describe some of the field experiments carried out at the Experimental Orchards, and to outline briefly those recently initiated.

Experiments of a more or less permanent character are as follows:—

(1) Apple, pear cherry, and peach stock trials. (The peach stock trials have been completed, and the trees removed, as they had reached a stage when they were no longer profitable, either from the point of view of fruit production or experimental data.)

(2) Manure trials with apples, pears, and peaches, and also autumn and spring manuring of apple trees.

(3) Tillage or cultivation tests.

(4) Various pruning tests with all varieties of fruit trees.

(5) Pruning in conjunction with thinning tests and its relation to biennial cropping.

(6) Apple stock trials in their relation to bitter pit.

(7) Experiments for the better control of codlin moth and other injurious insects and fungus diseases. In addition, there has recently been added another series of manure trials at Blackwood covering 20 plots of six trees, each manure trial to be replicated four times, together with pollenisation trials, pruning trials, and various methods of planting. Material is being worked up for an apple stock trial to test the comparative value of Northern Spy, Winter Majetin, Seedling, and own root stocks for the leading commercial varieties of apples.

At Fullarton, extensive citrus root stock trials, vine stock trials, and experiments with 12 varieties of almonds have been set out. Though this list does not cover all the experimental work undertaken, it will give some idea of the work in progress.

STOCK TRIALS.

It has long been realised that the influence of stock on scion and conversely, scion on stock, has a most important bearing on the future wellbeing of the tree, and is a most important problem in connection with fruit growing. It is no exaggeration to say that the success or failure of the orchard may depend on choosing the

right stock on which to work the trees, particularly with cherry, pear, and peach orchards. With the apple—as the Northern Spy stock is almost exclusively used—the difference is not so marked, though there is a great deal of controversy still as to whether the Spy is the best stock to use for apples.

CHERRY STOCKS.

In the tests set out at Blackwood, three each of five commercial varieties are worked on four different stocks:—Mazzard, Mahaleb, Kentish, and a combination of Kentish and Mazzard. Though there is still a difference of opinion as to the

Block 1.

Early Lyons on Mazzard. Note absence of point of union.

best stock for cherries, a glance through the trees at Blackwood will show that under local conditions the superiority of the Mazzard stock is outstanding. This stock comes from the wild sweet cherry (*Prunus avium*). It grows to a great height, and varieties worked on it make large trees, very uniform in growth, with clean, straight boles showing little or no indication of where stock and scion were united (see block 1). This stock also does not sucker. Trees worked on Mazzard are larger,

thrifter, and more productive when they come into bearing than on any other stock, and from present indications their productive life should be much longer than on other stocks. Some varieties are somewhat shy at first on Mazzard, but eventually they become profitable.

The Mahaleb stock (*Prunus mahaleb*) comes from Central Europe and Asia, where it grows in its wild state. It is quite different in appearance from the Mazzard and Kentish with leaves more like those of the apricot than the cherry. This stock has a dwarfing effect on varieties worked upon it, but generally trees on this

Block 2.

Early Purple Guigne Cherry worked on Mahaleb stock.

Note point of union.

stock come into bearing earlier than on Mazzard. The point of union between stock and scion is very marked, the stock generally outgrowing the scion (see block 2). Of the five varieties worked on this stock at Blackwood, St. Margaret is the only one that appears likely to thrive on it, as the four other varieties are showing signs of decay, and four trees in the row are dead. This stock may be better than the Kentish, but it is not so good as the Mazzard.

The Kentish cherry (*Prunus cerasus*) or sour pie cherry, has been used as a stock for many years, but in the tests it has proved very unsatisfactory. Trees worked on Kentish stocks rarely make good trees, though they come into bearing earlier than on Mazzard, with a tendency to over-crop with some varieties. The stock-scion union is very imperfect, the scion outgrowing the stock (see block 3); just the reverse of the Mahaleb stock. The Kentish stock, being of a dwarf character, produces much smaller trees than Mazzard or Mahaleb stocks, and it would appear that the life of the trees will be shorter than on the Mazzard. The Kentish stock also suckered sadly for many years.

Block 3.

Florence Cherry worked on Kentish stock.
Note point of union

With the combination stock—where the Mazzard root stock was used to give a strong growing habit and longevity to the tree, and the Kentish was worked directly on to the Mazzard with a view to inducing the earlier fruiting habit—the results have been rather interesting. The trees have grown as well as those worked directly on to the Mazzard, and they have produced rather better crops of fruit which ripen a little later than on the Mazzard, but the small intermediate piece of Kentish wood between the Mazzard stock and the upper portion of the tree has not developed to the same extent as the stock or scion, and has formed a small constricted area or waist a few inches above ground level (see block 4), and it would seem that in time the effect of this will be to shorten the life of the trees.

PEAR STOCKS.

Three each of four varieties of pears worked on pear seedlings and quince stocks were used in this test. The varieties on the seedling stocks have made fairly large trees; the stock scion union is perfect, and the trees are now cropping well, though for a few years the crops were lighter on this stock than on the quince, due to the fact, no doubt, that the trees were growing much more strongly. It would also seem that the size and quality of the fruit is better on the seedling stock than on the quince. The pear seedlings or free-growing stocks, as they are termed, are at

Block 4.

Early Lyons on Kentish on Massard.

Note constricted area of point of union.

present wholly provided from collections of seedling pears, the seed being obtained mostly from France. The seeds are collected from the pomace in the manufacture of perry. Like all seedling stocks, they show considerable differences, not only in vegetative characters but in root systems.

The quince stock is used for dwarfing purposes; probably the best type for general use being the true Anger's quince, and in the tests at Blackwood the trees are much smaller on this stock than on the seedlings. There would seem to be one

Block 5.

Note two apparently dead trees in foreground. These are Bourre Easter Pear worked on Quince stock. Same variety in background worked on Pear seedling.

Block 6.

Glou Moreau Pear worked on Pear Seedling.

serious disadvantage in using quince stocks for pears. Certain varieties of pears will not "take" directly on the quince, and of the varieties tried at Blackwood, the Beurre Easter is a complete failure on this stock. Stock and scion united, but the trees will not grow, though they may live for some years. Marie Louise, Souvenir de Congres, and Josephine de Malines are other varieties which are reputed to do badly on quince stocks. Now that the pear woolly aphis has made its appearance, it will soon be necessary to seek a pear stock resistant to this insect as is the Spy stock in the case of the apple. Some preliminary investigations have been made in this respect by the Horticultural Branch working in co-operation with Mr. H. N. Wicks.

It is hoped by a process of selection and elimination to obtain eventually a stock more or less resistant. Research is also being made in other directions, for it is realised that the future of the pear industry depends to a great extent on the solution of this problem.

PEACH STOCKS.

In this test there were four varieties of peaches—Red May, Elberta, Salwey, and Nicholls's Orange Cling—two of each on five kinds of stocks, viz.:—almond, Myrobalana plum, peach, apricot, and peach almond. Trees on the almond stocks grew well for some years, but the stock-scion union was very imperfect; large callouses developed which gummed excessively; the trees eventually developed dry rot so badly that large limbs broke off through their own weight, and at the time they were removed these trees were almost dead.

On the Myrobalana plum stocks the peach varieties almost without exception failed to grow at all. Stock and scion united, but only grew for a year or so. There was one notable exception in this section, and that was a Salwey peach, which developed on the plum stock equally as well as anything in the test. This tree grew so well that it was rather suspected that it had been planted deeply and had developed its own root system, but this surmise was found to be incorrect when the tree was removed, as plum suckers soon grew from the roots allowed to remain in the soil. This seemed to indicate some peculiar affinity between this particular plum stock and the peach, and to further test this point a number of stocks from suckers sent up by this plant have been raised vegetatively in the nursery.

On the peach stock all varieties grew well. The stock-scion union was perfect, and at the time the trees were removed they were in a sound, healthy condition with no signs of dry rot in the limbs when cut up. The apricot proved a failure as a stock for peaches, and the peach-almond hybrid, though better than the apricot, seemed to have no commercial value as a stock.

It would seem from the tests at Blackwood that the peach makes the best stock for the peach, and that trees worked in this way will have a longer productive life than when worked on other stocks. In some situations, and under certain soil conditions, the almond might prove a good stock, but that would be a matter to determine when planting, in view of soil conditions.

APPLE STOCKS.

These stocks have been tested more in relation to the incidence of bitter pit in the fruits than from the point of view of suitability of the various root stocks. Through the courtesy and generosity of the Fruit Division of the New South Wales Department of Agriculture we have secured a collection of the selections developed at East Malling of apple, cherry, and plum stocks. These comprise 12 trees each of English No. 1, Broadleaf Paradise, Very Dwarfing Jaune de Metz, Paradise No. IX., Semi-dwarfing Doucin No. 11, and Paradise No. 12, 13, 15, and 16; three types of Mazzard cherry stocks, F 1¹, 1² and 1³ and five types of plum stocks, Myrobalana "B," Black Damas "C," Brompton, Pershore, and Common Mussel—180 trees in all.

These have been planted in new land and it is intended from these mother stocks to raise vegetatively sufficient stocks on which to work a number of trees of the principal commercial varieties of the above kinds of fruits. These trees may then be distributed in the various fruitgrowing districts, and their suitability for our conditions thoroughly tested. Similar work is, by mutual arrangement between the different horticultural sections, also being carried out by the other State Departments of Agriculture, and should lead to very interesting and profitable results to the fruitgrowing industry of the Commonwealth.

At Blackwood we started two or three years ago on some preliminary research work in connection with Northern Spy apple and Myrobalana plum stocks. Northern Spy stocks were selected by District Horticultural Instructors from all apple-growing parts of the State and, with the co-operation of the owner, seven types of Myrobalana seedling stocks were selected from large beds of seedlings at Mr. H. N. Wicks's nursery. It is proposed to work up vegetatively numbers of these stocks and test their value with our more important commercial varieties of fruits on the same lines as with the East Malling stocks.

The importance of the root stock in the future well-being of the tree and orchard cannot be over-emphasised, and to obtain the best results it is essential that trees should be worked on the tested and most suitable stocks. It is possible to suit special soil conditions and situations by varying the type of root-stock to influence such characteristics as size of tree, health, vigor, fruitfulness, length of life, and resistance to disease. The stock may even influence the time at which the fruit-producing stage is reached, and even the intensity of color and flavor of the fruit.

MANURE TRIALS.

These were started at Blackwood on 1-year-old trees as far back as 1909, so that they have now been in progress for 24 years. There are three Cleopatra apples, three Glou Morceau pears, and three Elberta peaches in each test. There are 12 tests in all; three being check or control rows, and eight receiving applications of artificial manure and one of stable manure. A buffer or barrier row separates each test. To supply the three essential plant foods—nitrogen, phosphoric acid, and potash—sulphate of ammonia, superphosphate, and sulphate of potash respectively have been used, mostly in combinations in the following quantities per tree where these substances are specified in the schedule:—

Period.	Stable Manure.	Super.	Sulphate of Ammonia.	Sulphate of Potash.	Lime in combination.	Lime alone.
1909-1916...	56lbs.	1lb.	4ozs.	4ozs.	2lbs.	2lbs.
1917-1923...	70lbs.	1½lbs.	5ozs.	5ozs.	2½lbs.	2½lbs.
1924-1929...	1cwt.	2½lbs.	2lbs.	1½lbs.	5lbs.	7lbs.
1930-1933...	1cwt.	3½lbs.	3½lbs.	1½lbs.	5lbs.	7lbs.

The manures have been applied in the spring a few weeks before the buds burst into active growth. Our practice has been to spread it on the surface of the ground, covering an area equal to the spread of the branches, and keeping 2ft. or so from the stem of the tree. Immediately after spreading the manures have been ploughed in to a depth of 4in. to 5in. The data collected for the first few years covered measurements of the annual growth, circumference of the stem 9in. from the soil, and the weight of the crop. For some years, since the trees settled down to bearing, the two latter records only have been taken, but the crop records have been worked out in four grades to indicate the size and quality of the fruit, also its freedom from disease.

DATA RELATIVE TO APPLE TREE MANURE TRIALS—TEN-YEAR PERIOD, 1924-1932.
GOVERNMENT EXPERIMENT ORCHARD, BLACKWOOD.

COMPARATIVE YIELDS PER ACRE IN BUSHELS BETWEEN MANURED AND UNMANURED TREES.
Yield per Acre, 429.8bush., Calculated from the Mean Average Yield per Tree from Nine Unmanured Trees used as a Comparative Basis.

Test No.	Manures Applied.	Mean Average Yield per Tree over a Ten-Year Period in Lbs.	Mean Average Yield per Acre over a Ten-Year Period in Bushels.	Increase in Bushels per Acre over from Unmanured Trees.	Decrease in Bushels per Acre over from Unmanured Trees.	Remarks.
1	No manure	167.15	417.85	—	11.95	Bushels per acre calculated on the basis of 100 trees to the acre and 40lbs. per bushel of apples. All apples included.
2	Super.	154.12	385.3	—	44.5	
3	Super. and lime	169.58	423.95	—	5.85	
4	Super. and sulphate of potash	156.72	391.8	—	38.00	
5	Super., sulphate of potash, and sulphate of ammonia	198.81	497.0	67.2	—	
6	No manure	142.19	355.4	—	74.4	Quantities of manures applied as under:—
7	Lime, super., sulphate of potash, and sulphate of ammonia	253.9	634.75	204.95	—	
8	Lime	195.37	488.4	58.6	—	
9	Sulphate of ammonia and sulphate of potash	173.11	432.77	2.97	—	
10	Super. and sulphate of ammonia ..	224.35	560.87	131.07	—	
11	1cwt. stable manure	181.62	454.05	24.25	—	1923— Super. Potash. Sulph. Lime Alone. 1½lbs. 5ozs. 2½lbs. 2½lbs.
12	No manure	206.42	516.05	86.25	—	1924-29— 2½lbs. 1½lbs. 2lbs. 7lbs.
Average annual yield per acre from unmanured trees over 10-year period = 429.8bush.				1930-32— 3½lbs. 1½lbs. 3½lbs. 5lbs. 7lbs.		
Average annual yield per acre from trees receiving sulphate of ammonia over 10-year period = 531.35bush.						
Increase presumably due to sulphate of ammonia = 101.55bush. per acre. (Calculated from the mean average yield from 12 trees).						

In connection with the apple trials (Table 1), taking the average mean yield per acre from the nine unmanured trees as a comparative basis, it will be seen that super when used alone shows no increase over the unmanured trees, but actually less; and super and lime, though better than super alone, also actually less. When potash is added to super the yield is still decreased. The first increased yield per acre is shown when sulphate of ammonia is added to super and sulphate of potash, and the yield is further increased when lime is added to super, sulphate of ammonia, and sulphate of potash. Lime by itself alone shows an increased yield. When sulphate of potash is added to sulphate of ammonia the yield is considerably decreased in comparison with other tests in which sulphate of ammonia is used. Sulphate of ammonia added to super increased the yield considerably. Stable manure, on the other hand only increased the yield slightly.

Stated briefly, it would seem from the results of the last 10 years manuring at Blackwood that the use of superphosphate alone is uneconomical, that potash unless combined with superphosphate and sulphate of ammonia rather tends to decrease than increase the yield, and that nitrogenous manures when added to superphosphate or superphosphate and potash appear to give increased yields. It is where nitrogen has been applied that any increase in yield is shown, but whether this would be so if nitrogenous manures were used alone is not definitely shown in the Blackwood tests, as phosphoric acid and lime are the only compounds applied alone to separate tests.

In California, for instance, it is found that in any experimental work with nitrogenous fertilisers it is most important to provide adequate supplies of available phosphate and potash, and nitrogenous fertilisers will not produce the best results if the soil is deficient in these or other nutrients. These deductions are drawn purely from the crop data, and may not be altogether reliable for very many reasons. There are two main sources of error in field experiments.

(1) The inherent variation in the material that is dealt with—that is, in the trees themselves—and the variation which is due to outside factors such as soil and soil moisture conditions, and it is a difficult matter to estimate what is known as the “co-efficient of variability” due to these factors. A point to be noted is the effect of the fertilisers on the trees themselves. There are good grounds for believing that if a tree which is satisfactorily constituted makes good, healthy growth that satisfactory yields will result, and so long as the trees can be kept in this condition the results should be satisfactory. Where it is found that the application of fertilisers results in increased vigor in the tree itself it would seem reasonable to assume that crop yield will also improve.

In the tests at Blackwood trees receiving nitrogenous manures are much more vigorous and healthy than others under different treatments. From a study of the crop data it would seem also that nitrogenous manures increase the yield at least in the case of Cleopatras in the “off” year. In the tests to determine the best time to apply manures—autumn or spring—one set of trees receives a dressing in spring and another set in autumn. The test has been running for four years. From the data so far collected neither treatment seems to have any advantage over the other. An American experimenter sums up the position with regard to manuring fruit trees very clearly in the statement that, “Manuring has not made good trees into super trees, but it has made poor trees good, or kept good trees from becoming poor.” As previously mentioned, another comprehensive series of manure trials has been set out in which an attempt has been made to conform to standards now considered indispensable if the results are to have any scientific value.

SPRAYING TESTS.

Many reports have been published in connection with various spraying tests at Blackwood for different pests and diseases. The work in progress at the present time deals more particularly with Codlin Moth and Green Peach Aphis control. Another insect that appeared in great numbers last season, the Apple Leaf Hopper, is being closely watched with a view to control measures being adopted later on if deemed necessary.

Codlin Moth control experiments were started in 1925-26, and have been carried on every year since. Tests have been made to determine:—

- (1) If increased amounts of arsenate of lead would give increased control.
- (2) If the addition of ovicides such as Black Leaf 40 or Lime Sulphur would give more effective control.
- (3) If other substances, such as calcium arsenate, are more effective than arsenate of lead.
- (4) If the use of spreaders make any difference in control.
- (5) If the use of white oils increases efficiency.
- (6) The minimum amounts of white oils and arsenate that might be used without impairing efficiency with a view to reducing arsenical residue and spraying costs.
- (7) The use of other proprietary compounds such as "Destruxol," extract and emulsion, "Pysect," and "Clensel."
- (8) Testing various lures and methods of catching Codlin Moths to ascertain phases in the life history of the pest.
- (9) The use of chemically treated bandages for killing codlin grubs, &c.

All these points have been fully discussed in Departmental Bulletins.

GREEN PEACH APHIS.

Collaborating with Dr. Davidson, of the Waite Institute, the life history of this insect under our climatic conditions was worked out, and numerous sprays tried for its control. At Dr. Davidson's suggestion some years ago a quantity of tar distillate spray was imported from England, and this spray is now looked upon as the most effective winter wash to use against this insect. This season we are trying 10 different winter washes for the control of green aphid. One report on this subject has been published, and later on other reports will follow.

In this address some of the work being done at the Experimental Orchards at Blackwood and Fullarton has been briefly outlined with a view to stimulating interest in this work. The value of scientific research work is often underestimated and undervalued by the average farmer or fruitgrower. One of the outstanding features of modern industrial life has been the ease with which production in the secondary industries can be increased, and this is due to the fact that large, wealthy industrial concerns can employ trained specialists to improve methods of production and eliminate waste, and the increased profits constitute a sufficient reward. The farmer or fruitgrower, however, cannot afford to employ specialists or research workers, and even if he did no pecuniary reward awaits him to compensate him for the time and money devoted to the work. A new manufacturing process is rapidly adopted when discovered, but with farmers or fruitgrowers working as individual units scattered over a very large area ideas travel very slowly, and for these reasons the world over Governments have found it necessary to undertake research work, and also provide for the dissemination of new ideas.

APRICOT PRUNING EXPERIMENT AT LIGHT'S PASS.

[By J. B. HARRIS, Dip. Hort., District Horticultural Instructor.]

An experiment suggested by the Chief Horticultural Instructor, Mr. Geo. Quinn, to determine the relative values of the long and short leader systems of pruning when applied to Moorpark apricot trees was commenced in the orchard of Mr. P. B. Boehm, at Light's Pass, in August, 1930.

Prior to that date it had been suggested that the disease or physiological disturbance commonly known as "Gummosis," which attracted much attention by its prevalence throughout the district a few years back, might be partly due to a sap congestion in the vicinity of large cuts which are necessitated by the removal of very strong shoots and surplus limbs when the short or hard pruned leader system is followed.

At the time of writing, however, none of the trees have developed Gummosis with the accompanying "die back" as described in *The Journal of Agriculture* for July, 1932, and as it is commonly known in the Barossa district. The only evidence of gum which has so far appeared being a slight exudation of gum in two cases where a larval borer, probably *Maroga gigantella*, had attacked the trees.

Some interesting data, showing comparison of crop harvested and growth of the trees has, however, been recorded, and it is the intention to tabulate here these records, and to publish additional records from time to time, together with any records of gumming which may occur.

The layout of the plot is shown by the accompanying plan (Fig. I.), which also shows a history of the pruning of each tree since the 1930 winter pruning season, when the trees, which were planted in July, 1928, had made two seasons' growth. At the time of planting and during the following winter all the trees were short pruned.

Key to Fig. I.—x Denotes trees under test. ○ Denotes adjacent trees not included in test. ————— Denotes boundary fence. x/s Denotes trees which have been always "short" pruned. x/L Denotes trees which have been

"long" pruned in 1930 and each subsequent season. x/s/1930 Denotes trees which, in accordance with the alternating layout of the trees under test, should have been long pruned. These trees were short pruned in 1930 on account of weak growth, but have been long pruned each subsequent winter.

As six of the trees in the plot as originally set out—all of which were planted as "Moorpark"—have produced evidence by the nature of their growth and fruit that they are not of true Moorpark variety, it has been decided to eliminate them from future records. These trees are marked A, B, C, D, E, F, and include three long pruned and three short pruned trees.

The short leader system of pruning consists of selecting the most suitable growth for the extension of the main or secondary arm—generally this is a shoot from the highest bud, or an adjacent bud, on the leader left last year—and cutting it back to approximately one-third or one-fourth of its entire length. This tends to produce from one to three very strong growths, one or two of which have to

Figure II.—Long and Short Pruned Apricot Trees on Experimental Plot at Mr. B. Boehm's, Light's Pass, showing comparative size before pruning on 1/8/33. Short Pruned on left. Long Pruned on right.

be removed at their base, which involves heavy cutting during the following winter unless they are removed during the summer pruning. In either case the production and subsequent removal of these shoots seems to involve a sacrifice of the productive powers of the tree, a sacrifice which may, perhaps, be advantageously avoided.

The long leader system of pruning consists of leaving the leader unpruned until such time as it has produced a strong shoot from its own median region (i.e., about midway between its tip and its base), which it will readily do if left unpruned. This strong shoot which, in an entirely unpruned tree, would probably take the lead until weakened by another arising from its own median region, may be discerned as an outstanding green shoot about the month of November,

Figure III.—Apricot Tree in "Short Pruned" test, before Pruning on 1/8/33.

Figure IV.—Apricot Tree in "Short Pruned" test, after Pruning on 1/8/33.

Figure V.—Apricot Tree in "Long Pruned" test, before Pruning on 1/8/33.

Figure VI.—Apricot Tree in "Long Pruned" test, after Pruning on 1/8/33.

and the original leader may be cut back to the green shoot then, or the cutting back of the original leader may be left until the dormant winter season. In either case the selected leader is not "topped." This method of leader treatment, to which the name "long" pruning is applied, gives rise to a number of spurs along the leader rather than to the production of a few strong shoots as in the case of "short" leader pruning.

Fig. II. shows the comparative size, before pruning, of a "short" and a "long" pruned tree—trees H and G on the plan (Fig. I.)—on August 1st, 1933.

Figs. III. and IV. show the short-pruned tree H both before and after pruning on August 1st, 1933.

Figs. V. and VI. show the long-pruned tree G both before and after pruning on August 1st, 1933.

Crop Records.—The trees commenced bearing in the 1931-32 growing season, but as the crop throughout the district was disastrously affected by frost very little fruit was picked in January, 1932. The amount of fruit then picked was not recorded, but the fact was noted that the few fruits picked were almost all from the ends of leaders on the long-pruned trees. In January, 1933, the crop harvested from 16 long-pruned trees was 311lbs. net, whereas the crop from the short-pruned trees was 105lbs. net. The crop records in this case were supplied by Mr. P. B. Boehm, the owner of the orchard, who personally supervised the harvesting and weighed all the fruit picked.

Growth Measurements.—For the purpose of recording the comparative growth of the trees under the two different systems of pruning the circumference of the trunks at a height of 2in. above ground level was measured on October 5th, 1933, and the following record made. The trees were numbered as shown on the plan, trees A, B, C, D, E, F, being not included in this record:—

Tree No. 1 = 15"; 2 = 11 $\frac{1}{2}$ "; 3 = 16 $\frac{1}{2}$ "; 4 = 13 $\frac{1}{2}$ "; 5 = 12 $\frac{1}{2}$ "; 6 = 13 $\frac{1}{2}$ "; 7 = ";
8 = 14 $\frac{1}{2}$ "; 9 = 17 $\frac{1}{2}$ "; 10 = 14 $\frac{1}{2}$ "; 11 = 17"; 12 = 13 $\frac{1}{2}$ "; 13 = 15"; 14 = 13 $\frac{1}{2}$ "; 15 =
15 $\frac{1}{2}$ "; 16 = "; 17 = 16 $\frac{1}{2}$ "; 18 = 13 $\frac{1}{2}$ "; 19 = 11 $\frac{1}{2}$ "; 20 = 13 $\frac{1}{2}$ "; 21 = 13 $\frac{1}{2}$ "; 22 = 15 $\frac{1}{2}$ ";
23 = 16 $\frac{1}{2}$ "; 24 = 14 $\frac{1}{2}$ "; 25 = 16 $\frac{1}{2}$ "; 26 = 17"; 27 = 15 $\frac{1}{2}$ "; 28 = 13 $\frac{1}{2}$ ";

Thus the average girth of all trees under test is 14.673in.

The average girth of long-pruned trees is 15.288in.

The average girth of short-pruned trees is 14.057in.

As an indication that the disparity in averages is not due to single individual large or small trees it can readily be calculated that there are among the 13 long-pruned trees 10 trees above the girth average of the whole plot, whereas among the 13 short-pruned trees there are 10 trees below the girth average of the whole plot.

It has been said by some observers of the long leader system of pruning that it induces more abundant cropping during the early life of the trees at the expense of the crops of later years; how far this is so is a matter for extended trial, which may possibly lead to some modification of the system in later years. It should also be noted that the system is most applicable to young, vigorous trees.

ROSEWORTHY AGRICULTURAL COLLEGE

AFFILIATED WITH THE UNIVERSITY OF ADELAIDE.

GOVERNING COUNCIL:

A. M. DAWKINS, J.P. (CHAIRMAN)	
F. COLEMAN, J.P.	A. E. V. RICHARDSON, M.A., D.Sc.
L. T. COWAN, B.Sc.	PROF. A. J. PERKINS
D. A. LYALL, ESQ.	W. J. ADEY, ESQ.
H. C. PRITCHARD, A.F.I.A. (SECRETARY)	

PRINCIPAL:

DR. ALLAN R. CALLAGHAN.

A thorough and well-proportioned course of instruction in the theory and practice of General Agriculture, including Viticulture and Oenology, as well as all phases of Livestock Husbandry.

The Diploma Course includes three years of class-room tuition and practical work, and carries the academic distinction of R.D.A.

Excellent opportunities offered for the training of boys of 16 years of age or over. Splendid food and accommodation, hot and cold water. Ample sporting facilities, gymnasium, sports oval, tennis courts, and swimming pool.

FEES.—£50 per annum, which covers board and lodging, instruction, medical fee and dispensary expenses.

SCHOLARSHIPS.—Six scholarships are open for competition annually, each valued at £136 10s.

Write for further particulars, and prospectus, to—

Agricultural College,

ROSEWORTHY.

THE AGRICULTURAL FEATURES OF *PHALARIS TUBEROSA* AND ALLIED FORMS.

[By H. C. TRUMBLE, M.Agr.Sc. (Agronomist, Waite Agricultural Research Institute).]

A. INTRODUCTION.

The species of the *Phalaris* group, commonly known as the canary grasses, are for the most part adapted to climatic conditions of the Mediterranean type. A notable exception is *P. arundinacea* L. which inhabits the northern temperate regions. The remaining forms of agricultural importance are found chiefly in the Mediterranean zone, Chili, and in California, where conditions of winter rainfall and summer drought prevail.

According to the *Index Kewensis* 26 species of the genus *Phalaris* have been recorded. There is none indigenous to the Cape Province of South Africa or to Southern Australia, where the climatic conditions are similar to those of Mediterranean countries, and suitable for the development of *Phalaris* species.

Only two species have been cultivated extensively in the Northern Hemisphere. The annual canary grass (*P. canariensis* L.) has been grown for several centuries in Mediterranean countries for its grain, the destiny of which provides an ornithological label for the group. The perennial reed canary grass (*P. arundinacea*) has proved a valuable hay and pasture species on wet soils in both Europe and North America. The genus has attracted attention in Southern Australia because *P. tuberosa* L., a closely related form, has proved a suitable basis for pasture improvement over a comparatively extended area.

A total of eight *Phalaris* species has been grown and studied at the Waite Institute. Of these *P. tuberosa* has been outstanding, but *P. coerulescens* Desf. has given promising results in trials of a preliminary nature. Both forms are winter-growing perennials from the Mediterranean region. The remaining perennial species, *P. arundinacea*, is unsuited to the climatic conditions at Adelaide, owing to the summer incidence of its growth. The remaining five species—*P. canariensis*, *P. minor* Retz., *P. paradoxa* L., *P. Lemmoni* Vasey. and *P. angusta* Nees.—are suited to the climatic conditions of the South Australian wheat belt, but are not sufficiently permanent under grazing to justify their use as pasture plants. *P. angusta* appears to be adapted to swampy or sub-swampy areas of a saline nature.

The tribe Phalarideae contains in addition to the *Phalaris* group the *Ehrharta* species (veldt grasses) of South Africa and *Microlaena stipoides* (Labill.) R.Br. (weeping grass) of Southern Australia. All three genera inhabit regions with temperate winters and dry summers where seeded pastures are as yet comparatively rare. An agriculturally important characteristic of the tribe is the readiness with which the single mature floret falls from the spikelet, resulting in shedding of the "seeds" at maturity.

B. HISTORICAL.

(a) *Use of Phalaris arundinacea in temperate countries.*

P. arundinacea was apparently first investigated in Sweden, where Hesselgreen (1) reported on its palatability to ruminants and to horses in 1749. There is evidence that this species was in general use as a fodder plant in Southern Sweden at the time. It has apparently been cultivated to a limited extent in Western Europe for a century, and in North America for 50 years. In the United States an expansion in the acreage of this grass has been recently observed (2).

The agricultural characters of *P. arundinacea* and the results of agronomic trials with this species have been described by Schoth (2), and more recently by Wilkins and Hughes (3). These publications are of interest because many of the results obtained with *P. arundinacea* agree closely with South Australian experience of *P. tuberosa*. The most striking points of agreement are as follows: (1) the susceptibility of the seedlings to competition from weeds and other grasses; (2) the longevity of the established stands; (3) their comparative freedom from intrusive weeds, diseases, or insect attack; (4) the importance of cutting before flowering to obtain good quality hay, and (5) the readiness with which the mature seeds fall. In both species commercial seed frequently possesses a low rate of germination, due chiefly to harvesting at an immature stage in order to avoid shattering.

The essential differences between the two grasses under the conditions at the Waite Institute are as follows:—(1) The two species differ in the incidence of their seasonal development; (2) the seeds of *P. arundinacea* are small (560,000 per pound), germination and establishment are slow; whereas the seeds of *P. tuberosa* are larger (about 300,000 per pound), and the germination and establishment of this species are more vigorous; (3) the foliage of *P. arundinacea* tends to be rather fibrous compared with that of *P. tuberosa*, which is finer, denser, and more succulent. Both species are capable of hay yields comparable to those obtainable with winter cereals. Seed production in each grass varies from 30lbs. to 150lbs. per acre.

The reason given by American workers for the limited cultivation of *P. arundinacea* is the readiness with which the seed shatters as it ripens, rendering harvesting difficult and the seed costly. The seed of *P. tuberosa* has been comparatively expensive for the same reason. Selection for non-shattering and high seed producing types of *P. arundinacea* is in progress in the United States (2).

(b) *Phalaris arundinacea* in South Australia.

Phalaris arundinacea, whilst not adapted to South Australian conditions generally, has displayed a high degree of vigor and permanence in small trials on the irrigated swamps of the Murray River (4). At the Waite Institute, individual plants persist as perennials despite the dry summer conditions, but are low in productivity. The importance of this species in Southern Australia lies in its obviously close relationship to *P. tuberosa*. Jenkin has recently shown (5) that the two species may readily be inter-crossed, and the cross has also been effected at the Waite Institute. Jenkin carried his hybrids to the fourth generation, and produced fertile segregants of agronomic value. The evident close relationship between the two forms suggests interesting possibilities in the breeding of hybrid forms, particularly for irrigated areas.

(c) *Early history of Phalaris tuberosa* in Australia.

The development of *P. arundinacea* in temperate countries, although limited, has been clear cut and positive. On the other hand, the use of *P. tuberosa* has been attended by confusion, and the origin of the grass as developed in Australia is wrapped in obscurity. Since the recognition of its agricultural value at Toowoomba, Queensland, towards the end of the last century, many conflicting reports and views concerning its history have appeared.

The Mediterranean form of *P. tuberosa* (previously known as *P. nodosa* and *P. bulbosa*) was described by Linnaeus in 1771. Representatives of this type were collected by the writer in Morocco and in Palestine during 1928, and have been found to differ from the Australian types in agricultural features, being considerably earlier in flowering, taller, coarser, more stemmy, less robust, and less densely tillered. The spikelet and general botanical characters, however, are essentially the same, although the appendage of the first sterile floret—a feature

of the Mediterranean types—is frequently absent in material of Australian origin. The Mediterranean forms of both *P. tuberosa* and *P. coerulescens* appear to have been regarded as too coarse to be of value as pasture plants.

The types of *Phalaris tuberosa* now grown in Australia, or material capable of giving rise to these types, was apparently introduced into Queensland in 1884. A packet of seeds labelled *Phalaris commutata*—a name which has since been abandoned by taxonomists—was obtained, together with samples of various other grasses, from the United States Department of Agriculture. The original sample of *Phalaris* was apparently collected in Italy and grown for some years at New York before being sent to Toowoomba. The grasses received from America were sown in the nursery of the Toowoomba Botanical Gardens, but “the frost killed all . . . except *Phalaris commutata*.” The ground was required for other purposes, and the grass was removed and deposited on a rubbish heap, after which it was apparently forgotten until a vigorous development was observed several years later. Seed from these plants was subsequently distributed from Toowoomba to the various States of the Commonwealth, to South Africa, to California, and even to Italy.

Whether the agriculturally valuable types of *Phalaris tuberosa* now in use are to be found in Mediterranean countries, or whether these were produced from the imported material by selection, mutation, or hybridization during the years following introduction can only be determined by plant exploration in the Mediterranean region itself together with controlled hybridization experiments. That the Australian types have been derived by the hybridization of less valuable forms or species has been suggested by Ewart (6) and by Kennedy (7). The theory was rejected fairly recently by Allan and Zotov (8) on the basis of lack of evidence to support it, but Jenkin (5) still more recently contends that the theory of hybrid origin is not unreasonable, and suggests hybridization between *P. arundinacea* and the Mediterranean *P. tuberosa* followed by back-crossing to the latter as the mode. The author, whilst agreeing that the theory of hybrid origin is not unreasonable, does not support Jenkin's suggestion regarding the mode on the following grounds:—

Firstly, the hybrid forms produced by Jenkin and illustrated in Plates Ib, IIa, and IIc of his paper (5) are by no means identical with the majority of forms included in a comprehensive collection of Australian types grown at the Waite Institute. In particular, the lobed inflorescence depicted in Plate IIc is unlike the typically spike-like, non-lobed panicle which characterises Australian material; in fact Plate IIg, which depicts Jenkin's *P. tuberosa* parental type is remarkably similar in its shape and non-lobed character to the most typical forms of the Waite Institute collection. Jenkin's parental *P. tuberosa* was obtained from Messrs. Vilmorin-Andrieux et Cie., of Paris, under the name “*Phalaris (nodosa vel bulbosa)*, Toowoomba Canary Grass,” and this, according to Messrs. Vilmorin “came from a sowing made in 1904.” As this was the very year in which publicity was given to the Australian *Phalaris* and the names “*nodosa vel bulbosa*” and “Toowoomba” have been used by Messrs. Vilmorin, it is not entirely unlikely that Jenkin's seed was originally obtained from Australia. The material personally collected by the writer from the Mediterranean does not correspond in all respects with the Vilmorin material, and the hybrid types of Jenkin are of a character intermediate between *P. arundinacea* and the Australian forms rather than identical with the latter.

Secondly, there are evident affinities between the annual *P. minor* and the perennial *P. tuberosa*, and much confusion between the two species has occurred in Australia in the past. Both these species and *P. arundinacea* possess 28 somatic chromosomes and 14 bivalents in the heterophytic metaphase.*

**P. minor*—F. S. Oldham, unpublished data, Waite Institute, 1932.

Sufficient evidence has been accumulated at the Waite Institute to indicate natural hybridism between *P. minor* and one or other of the perennial forms, and hand crosses between *P. arundinacea* and *P. minor* have been readily effected during the past season. Pending further evidence from the progeny of these and other hybrids, the role of hybridism in the evolution of Australian *P. tuberosa* must still remain hypothetical, and the question an open one.

Thirdly, whereas the theory of hybrid origin is attractive, there is still the evident possibility that the Australian forms are variants or ecotypes isolated from populations of *P. tuberosa* occurring naturally in the Mediterranean region.

(d) *Conflicting taxonomic views.*

A crucial point in the differentiation of *Phalaris* species has been the nature of the sterile florets at the base of the single fertile floret within each spikelet. In the annual *P. minor* the first sterile floret consists of a minute scale without an inner appendage, whereas the second sterile floret possesses a conspicuous appendage within the scale. In the Mediterranean specimens of *P. tuberosa** and in many of the Australian specimens, both scales contain an appendage. The Australian types, however, vary considerably in this character, and the appendage of the first sterile floret may be well developed, minute, or entirely absent as in *P. minor*. Lack of appreciation of this fact has resulted in much confusion taxonomically.

Thus Hackel, the noted European agrostologist, described the grass as a new species, *P. stenoptera* Hack., owing chiefly to the absence of this appendage in material sent to him by Ewart; whereas Kennedy, whilst accepting the name *P. stenoptera*, found that the appendage was present in his material, and explained the discrepancy on the supposition that Ewart had sent seeds of *P. minor* and the vegetative parts of *P. tuberosa* to Hackel. With this explanation Allan and Zotov, in their survey of the taxonomic position based partly on work by Hubbard, agree. The explanation is entirely incorrect, however. Sterile florets similar to those of *P. minor* do occur on perfectly normal plants of *P. tuberosa*, and in fact some promising agricultural strains of this species produce "seeds" of this type. Individual plants of *P. tuberosa* moreover yield progeny which show a range of second sterile florets varying from appendage absent to appendage well developed. This character, therefore, cannot be used as a means of species differentiation, and Ewart's specimens were probably authentic, and not mixed as was suggested by Kennedy.

It remains to explain the occurrence of seeds with *P. minor* characteristics on typical *P. tuberosa* plants, and this must await further investigation. The following information is suggestive, however.

Seeds of the original material grown at Toowoomba and supplied by the Curator, Mr. R. R. Harding, to Dr. Kennedy showed first sterile florets with appendage well developed, minute, and absent. The same condition was apparently found in specimens subsequently grown at Davis, California.

Of two specimens forwarded to Mr. Bailey at the Brisbane Gardens one proved to be *P. arundinacea* and the other *P. tuberosa*.

Commercial seeds of *Phalaris* have been notoriously mixed for many years; this has led to confusion and a restricted use of the grass.

Seeds of *P. arundinacea* from Southern France have produced plants of both *P. arundinacea* and *P. tuberosa*.

Hybrid forms have occurred in the Waite Institute collection, which have given rise to both perennial and annual types.

* Very limited material of *P. tuberosa* has so far been obtained from Mediterranean sources direct.

Simple contamination or mixing of *Phalaris* seeds has probably occurred fairly frequently, being facilitated by the resemblance between the inflorescences of the various forms and the readiness with which the mature seeds shatter. The definite cases of hybridism and segregation which have occurred, however, indicate that the three types—*P. arundinacea*, *P. tuberosa*, and *P. minor*—will inter-cross, and cytological evidence supports this view.

(e) *History of Phalaris tuberosa in Southern Australia.*

The history of *P. tuberosa* in Southern Australia appears now to be fairly well defined. It first came under notice in the Southern States in November, 1904, when an extract of a report by the Curator of the Toowoomba Gardens, drawing attention to the agricultural possibilities of the grass, was published in the *Garden and Field* of November 19th of that year (9). Portions of this extract referred to the importation of "*Phalaris commutata*" in 1884, its persistence as sole survivor of frosty conditions, its removal to a rubbish heap, and its subsequent spread to various parts of the nursery. It was noted that "During the 1893 flood the roots were in a bog for six weeks, and the only difference it made was the foliage was slightly yellow, but kept growing all the time."

The report concluded with a recommendation that "a plot of ground be prepared outside the nursery, convenient to public view, and that this grass be planted for the purpose of distribution, and that publicity be given that plants can be obtained at the gardens."

This apparently is the earliest authentic record of the grass so far as Southern Australia is concerned, and was the first occasion on which *P. tuberosa*, or *P. commutata* as it was then called, came under the notice of the agricultural community in this State. It appears that various people wrote for the seed, which was sown in South Australia for the first time in 1905.

The grass received much publicity during the next few years, and samples of the seed were sold at prices ranging from 5s. to £1 per ounce. There is evidence that numerous small plots were sown more than 20 years ago in different parts of South Australia, Victoria, and New South Wales. In South Australia the majority of these are persisting at the present time in the winter rainfall belt, receiving over 17in. of rain per annum.

Extensive areas of *Phalaris tuberosa* have been established by relatively few growers, however. In South Australia until very recently only one farmer, Mr. G. K. G. Warren, of Springfield, Williamstown, possessed more than a few acres of the grass. Mr. Warren's father, the late Mr. William Warren, sowed half an ounce of the seed during the early years of its introduction, and following a high degree of success, collected seed first by hand, then by scything, a tarpaulin being dragged along to catch the falling sheaves and the readily shedding seed. By gradually extending the area under the grass, approximately 100 acres were ultimately established, and this until 1930 comprised the only appreciable area of the grass on any one farm within the State. During the last three years, however, following the successful establishment of five acres by Mr. L. J. Cook at the Government Experimental Farm, Kybybolite, and successful trials carried out in various parts of the State by the Department of Agriculture and by the Waite Institute, the area sown with this grass has been considerably extended.

In Victoria, Mr. Alan F. Wilson established 16 acres in 1919, and with seed from this stand gradually extended the area until at the present time approximately 100 acres have been established.

In New South Wales the grass has been grown to a greater extent than in the southern States, particularly in the tablelands districts where it is valued for its winter development and resistance to summer drought. Several growers have

submitted seed samples to the Waite Institute per favor of the Agrostologist, Mr. J. N. Whittet, and these have been grown during the past two seasons. Little difference in regional type was evident, but all samples gave rise to typical variants of *P. tuberosa*.

The drought-resistance, autumn development, and adaptability to grazing conditions of *Phalaris tuberosa* became apparent at the Waite Institute during the progress of early trials carried out in 1925, 1926, and 1927, when this grass was known as *Phalaris bulbosa* L. In 1928, and again in 1929, areas of 1—4 acres were sown with seed bought commercially as *P. bulbosa* (= *P. tuberosa*), which, however, proved to be the annual species *P. minor*. This experience had been gained as early as 1909 by G. T. Griggs, of Meadows (S.A.).

In 1929 the general position in South Australia was hopeless. From seedsmen at the time nearly half the samples obtained were pure *P. minor* or mixtures of *P. tuberosa* with *P. minor*. It was found impossible to identify with absolute certainty every seed of either species, as the characters normally employed, such as color, shape, pubescence, and the presence or absence of the appendage to the first sterile floret were found to be so inconstant, particularly in *P. tuberosa*, that certain identification from seed characters alone was not in all cases possible.

The only thoroughly reliable character has been the pink root tip character (10) for *P. minor*. This is positive for *P. minor* or its F1 hybrids. So far, in over 300 samples tested, no pink root tips have been observed on true non-segregating *P. tuberosa* types, nor have any seeds giving rise to white tips produced true breeding *P. minor*.

The pink root tip character has enabled elimination of *P. minor* to be readily effected, and during the last three years, 1930-32, a definite expansion in the use of the grass in South Australia has been made possible by the location and use of reliable sources of truly perennial and persistent types of *P. tuberosa*.

C. THE ROLE OF *PHALARIS TUBEROSA* IN THE DEVELOPMENT OF PASTURES IN SOUTHERN AUSTRALIA.

(a) *Environmental factors and objectives.*

The climatic conditions under which the pasture investigations of the Waite Institute have been carried out are representative of an extensive region in Southern Australia. The environmental conditions of this region are described in separate publications (11, 4); the principal differences between this type of environment and that characteristic of temperate regions such as Western Europe, New Zealand, and South-Eastern Australia are the more arid summers and more favorable winters of the former. Owing to the failure of European pasture plants such as cocksfoot, white clover, red clover, and English types of perennial rye-grass in this environment, other species have been sought. The search for suitable pasture types has been conducted with the following essentials in view:—

1. Persistence under comparatively arid summer conditions.
2. A capacity for adjustment to widely varying soil types.
3. Persistence and stability under grazing and varying conditions of management.
4. A capacity for high production under grazing and over a sustained period of the year.
5. Aggressiveness and ability to compete with naturalised plants.

(b) *Phalaris tuberosa* as a suitable perennial grass type.

Trials carried out under widely varying soil and climatic conditions and reported on elsewhere (4) have indicated that the Hawke's Bay (New Zealand) type of perennial rye-grass, *Phalaris tuberosa*, Wimmera rye-grass and subterranean clover form a suitable basis of pasture types for the region under review. In these trials *Phalaris tuberosa* has been the only species to persist vegetatively at all centres. Under conditions of high soil fertility and effective summer rainfall, perennial rye-grass of the Hawke's Bay or reliable Western District type has proved more productive under grazing than *Phalaris tuberosa* during the first three seasons of the pasture, but the latter species is more drought-resistant and more resistant generally to adverse climatic conditions and declining soil fertility.

In comparison with the two annual species, subterranean clover and Wimmera rye-grass, the annual period of production of both *P. tuberosa* and perennial rye-grass is considerably wider and the stability of the pasture greater.

The particular advantages of *Phalaris tuberosa* lie in its drought-resistance, permanence and stability when established, its adaptability to varying soil types—provided that the subsoil is reasonably deep and retentive of moisture—and its adaptability to varying conditions of management, ranging from rotational grazing to pure hay.

(c) *Reasons for the restricted use of Phalaris tuberosa during previous years.*

In view of the advantages given above, it becomes pertinent to ask why, during the fifty years since its initial introduction into Australia or the thirty years since its first popularization, the grass has not been more widely used.

The readiness with which the seeds shed at maturity, and the poor capacity for spreading on non-cultivated land, have both seriously restricted the use of *P. tuberosa*. There is evidence that in South Australia, where the conditions are well suited to its development, the grass was becoming popular shortly before the war, and the intervention of the war period 1914-18 probably acted as a check on its development, especially from the point of view of the younger and more enterprising generation. During the post-war period the unfortunate confusion between *P. tuberosa* and the annual *P. minor* has led to a general lack of appreciation of the qualities of the perennial species. Perhaps the most important and most fundamental of the several inhibitory factors, however, has been the little realised fact that *P. tuberosa* is highly sensitive to competition, particularly from the rye-grasses, during the year of establishment. Many failures with this species have been due to its inclusion in mixtures containing comparatively large quantities per acre of rye-grass. Investigations at the Waite Institute have recently shown that in order to obtain a vigorous development of *Phalaris tuberosa* in the first season it is necessary to eliminate from the mixture or greatly restrict the seeding of rye-grass, which forms the basis of most pasture mixtures.

Additional agents of suppression are vigorous weeds such as Cape dandelion (*Cryptostemma calandulacea*), barley grass (*Hordeum murinum*), wild oats (*Avena fatua*), and soursob (*Oxalis cernua*). The presence of these plants in poorly prepared or weedy ground effectively inhibits the establishment of *Phalaris tuberosa*. Where these have been eliminated by careful soil preparation the expense involved in establishing the pasture has usually been appreciable, and the invariable inclusion of rye-grass in the mixture is readily understandable. Owing to the high price of *Phalaris* seed (until recently 5s. 6d. to 7s. 6d. per lb.), its frequent low viability and unproven claims, it is perfectly natural and rational that perennial rye-grass or Wimmera rye-grass should be included as a safeguard, if not as the chosen basis of the pasture.

Figure 1.—Pasture sown May, 1931, with *Phalaris* 50 per cent., rye-grass 50 per cent. Herbage, 1931, contained *Phalaris* 7 per cent., rye-grass 93 per cent. Herbage, 1932, contained *Phalaris* 35 per cent., and rye-grass 65 per cent.

Figure 2.—Pasture sown May, 1931, with *Phalaris* 75 per cent., rye-grass 25 per cent. Herbage, 1931, contained *Phalaris* 21 per cent., rye-grass 79 per cent. Herbage, 1932, contained *Phalaris* 65 per cent. and rye-grass 35 per cent.

The competitive effect of perennial rye-grass is shown in Figs. 1, 2, and 3. It is shown by Cashmore (12) that differences in the structure of the root systems of the two species help to explain the depressing influence of the rye-grass.

D. THE AGRICULTURAL FEATURES OF *PHALARIS TUBEROSA*.

(a) Seed germination.

The seed germination of commercial samples is usually between 40 and 70 per cent., and rarely much above 70 per cent. Quite frequently the viability is below 40 per cent., but the seed in these cases is probably several years old, or has been harvested in an immature condition. Samples picked by hand at the Waite Institute invariably give a viability of 90 to 100 per cent., whereas samples harvested by a field implement such as the binder or stripper give lower values. These, and the low values of commercial samples generally, appear to be due to the presence of immature seed unavoidably harvested owing to its readily shattering nature.

Figure 3.—Pasture sown May, 1931, with *Phalaris* 100 per cent.

Figures 1-3.—Development of three swards at the Waite Institute during August, 1932. Each was sown in May, 1931, with the same number of viable seeds per plot (approximately 16 lbs. total seed per acre), but with varying proportions of *Phalaris tuberosa* and perennial rye-grass.

The optimum range of temperature for the germination of *P. tuberosa* seeds is 15 to 25°C. Alternating temperatures are apparently not necessary. Higher figures are usually obtained in sand or soil than on filter paper, due to the fact that the "seeds" are rather flat or lens-shaped, and tend to be enveloped in a film of water, which excludes air, when the seeds are placed on filter paper. This is particularly true of poorly filled grains. By using sieved sand at 60-70 per

cent. moisture saturation and maintained at 15-25°C. the maximum germination percentage is attained. This renders the detection of pink tips (*P. minor*) difficult, however, and in routine tests conducted at the Waite Institute the samples are germinated both in sand and on filter paper.

The results of an investigation in which seed samples of varying origin were tested on filter paper as against sand are given in the following table:—

Odds that mean germination percentage in sand is significantly greater than that on filter paper:—At 7 days, 9999 : 1; at 21 days, 1110 : 1.

The effect of temperature on the germination of *P. tuberosa* was investigated by means of a multiple temperature incubator of fourteen compartments. The mean temperature of each compartment for the period of the test is given in Table II. The fluctuation in temperature was slight; the maximum amplitude was 2.0°C., but in most cases the total fluctuation of any compartment was less than 1.5°C., or 0.75°C. from the mean. Petri dishes 9cm. in diameter were each provided with 50 gms. of sterilised quartz sand of 1mm. diameter or less, maintained at 70 per cent. of its water-holding capacity. Each test consisted of duplicate lots of 100 seeds, and an incubation period of 21 days was allowed.

The following table summarises the results obtained:—

After-ripening is frequently necessary with *P. tuberosa* seed, particularly when grown in cool moist habitats, or harvested in an unusually cool moist summer. Seed harvested from a Victorian locality during the 1930-31 season and again during the 1932-33 season gave, when germinated at the Waite Institute some weeks after harvest, unusually low germination percentages. During the subsequent storage period, however, the samples gradually improved in viability. The germination figures for the two samples are given in Table III.

TABLE III.—*Showing Improvement of Certain Samples of Phalaris tuberosa after Harvest.*

* Gb 290 represented seed of Gb 276 dried off in the sun.

After-ripening is apparently necessary only where the seed has developed under relatively cool moist conditions, and may be hastened by exposing to warm, dry conditions after harvest.

The evidence concerning germination indicates that satisfactory germination may be attained over a fairly wide range of temperature—10 to 28°C. (50 to 80°F.)—with an optimum temperature in the neighborhood of 20°C. (68°F.). The seeds are sensitive to unfavorable conditions of excess moisture or inadequate aeration, as evidenced by filter paper results, and unsatisfactory germination occurs in water-logged soil or where the seeds are not sown fairly close to the surface. In practice the seeds should be thoroughly covered but not to a greater depth than $\frac{1}{2}$ in. on loamy or heavy soils, and not deeper than $\frac{1}{4}$ in. on sandy soils. Harvested samples may be low in viability, due to harvesting as little as two or three days before the optimum stage, and after-ripening may be necessary in the case of seeds which have developed under cool moist conditions. After-ripening does not occur in seeds harvested in a green condition, however, but is only effected in fully developed and apparently mature seeds.

(b) Establishment and Seedling Development.

The seedling development of *P. tuberosa* is vigorous compared with that of perennial grasses such as cocksfoot, *Danthonia*, Yorkshire fog, and perennial veldt grass, but it is only half as vigorous as that of perennial rye-grass (12), which in turn is considerably less active in establishment than Wimmera rye-grass.

Figure 4.—Development of *Phalaris tuberosa* at Gepp's Cross on May 10th, 1932.
Sown as a pure sward on June 4th, 1931.

Figure 5.—Development of *Phalaris tuberosa* and Dwalganup early subterranean clover
at Gepp's Cross on May 10th, 1932. Sown as a mixture on June 4th, 1931.

The sensitiveness of *P. tuberosa* to competition has been established by the work of Trumble and Davies (4). To their evidence must now be added the data of Cashmore (12), which show that the inclusion in the seeds mixture of only 8lbs. or 12lbs. per acre of perennial rye-grass tends to suppress very effectively the establishment of *P. tuberosa* and to reduce its yield during the first and second seasons to negligible quantities. Furthermore, as little as 4lbs. per acre of perennial rye-grass sown with 12lbs. per acre of *P. tuberosa* depressed the yield of the latter by 75 per cent.

The nature of the depressing influence of rye-grass on *P. tuberosa* during the year of establishment is at present under investigation. Whilst the structure of the root system is of evident importance in permitting greater physiological activity on the part of the rye-grass in the surface layers of soil, the roles of (1) competition for nutrients and (2) depression arising from the root respiration of the rye-grass have not yet been fully investigated.

From the practical point of view it is essential that seedlings of rye-grass or cereal cover crops be eliminated or employed with great caution in the establishment of *P. tuberosa*. Moreover, weed competition should be reduced as much as possible. On the other hand, the presence of a suitable legume, such as subterranean clover, in the higher rainfall country bordering the wheat belt, early subterranean clover in the cereal areas, and white clover under irrigation is desirable and definitely advantageous to the grass, even on soils of moderate to high fertility. Evidence of the value of early subterranean clover at Gepp's Cross (South Australia) on a rainfall of 18in. is shown in Figs. 4, 5, and 6. Detailed evidence of the value of legumes in association with permanent grasses is given in a separate publication (4).

(c) *Seeds rates and methods of establishment.*

Owing to the relatively small size of *P. tuberosa* seeds (approximately 300,000 per lb.) heavy seed rates are not usually required. Even if the germination is as low as 30 per cent., each pound of seed will contain 90,000 viable seeds, or sufficient to provide two viable seeds per square foot of soil. With seed of good viability, there are generally 220,000 viable seeds per lb., or sufficient to supply five viable seeds per square foot. The establishment rate under reasonably favorable conditions and in the absence of competition is usually about 40 per cent., so that theoretically 1lb. of seed per acre is capable of providing 1-2 plants per square foot, according to viability. On fertile soils 4 vigorous seedlings per square foot appear to be ample, indicating seeding rates of 2-4lbs. per acre. On poor sandy soils 1-2lbs. per acre or even less, when established with subterranean clover, may be found satisfactory provided good seed is employed and sown effectively, with due regard to tilth and depth of seeding.

Adverting to the work of Cashmore cited above, a seeds rate of 16lbs. per acre produced 22.2 seedlings per square foot during the first season. After the succeeding summer period, and at the commencement of the second winter these had thinned out to 3.0 plants per square foot, but provided a sward of 100 per cent. ground cover (*vide* Fig. 3) during the second winter. There appears to be no necessity for high mortality, which here occurred to the extent of 87 per cent., because in a collection of 25,000 single plants of true *P. tuberosa* set out 2 to 3 links apart at the Waite Institute, no single death has occurred during the past three years. The mortality found in dense seedlings is probably due to inter-plant competition for water, nutrients, soil, oxygen, and light. With sparse seedlings in the absence of competition from other plants and under suitable environmental conditions, mortality is low to negligible. Sparse seedlings, moreover, permit a higher degree of individual plant vigor—a desirable feature under conditions of summer

Figure 6.—The effect of early subterranean clover on the development of *Phalaris tuberosa*, along the edge of an adjoining plot of the latter on July 24th, 1933. The plots were established on June 4th, 1931.

drought. All of this points to seeds rates considerably lower than those employed in temperate countries, and lower than the rates until recently thought to be necessary in South Australia. Their adoption in the case of *P. tuberosa* presupposes the absence of competition from weeds or other grasses, and is made possible by the comparatively favorable temperatures of autumn and early winter in Southern Australia, and by the capacity of single plants of *P. tuberosa* to attain an ultimate diameter of several feet by means of sub-aerial rhizome development.

P. tuberosa seed may be effectively established by mixing with superphosphate immediately before sowing and applying to the soil surface by means of a drill or fertiliser distributor. It is preferable not to sow the seed in drill rows. The seed should be allowed to drop on to a well-prepared surface of a slightly cloddy nature, or ridge-rolled. Light brush harrowing with a chain, wire-netting, or boughs is usually sufficient to cover the seed, which must not be buried deeply. Seeding should be carried out as early as possible after the break of weather in autumn.

A method commonly employed at the Waite Institute is to sow the seeds at the rate of 150 per square foot or 1oz. to 14 square yards in seed boxes or nursery beds in March-April, six to eight weeks before the break of weather. An ounce of seed, sown and watered carefully, will provide sufficient seedlings to plant an acre if the seedlings are planted at 2ft. x 2ft. intervals. The method enables vigorous plants to be obtained during the first year, and planting may be deferred until well into the winter if difficulties are experienced in preparing the land. It also permits planting under water-logged conditions, and in subterranean clover land if desired. The cost of seed per acre in this case is negligible, but the cost of planting is a serious item. There is probably some scope for this method on small, intensively cultivated areas, particularly where *P. tuberosa* is being subjected to preliminary trial, and where small capital rather than lack of labor restricts the utilisation of the grass. Planting with root cuttings is effective but tedious.

Whether the grass is sown or hand-planted, a suitable strain of subterranean clover should be sown with the *Phalaris* at the rate of approximately 4lbs. per acre, if pasture legumes do not already occupy the land.

(d) Productivity and persistence.

Total production in the seeding year is usually low, and infrequently exceeds 10cwts. per acre of hay. Two or three intermittent grazings of short duration are advantageous in restricting competition from annual plants which tend to dominate the pasture during the spring. Grazing during the first year should be adopted solely in the interests of the developing *Phalaris* plants, as these are established with a view to occupation for many years. Grazing should not be commenced until the seedlings possess at least three tillers per plant, usually about 10 weeks after seeding, and a reliable guide in stocking is to maintain a cover of grass approximately 2in. to 4in. in height. Neither hard grazing nor allowing the pasture to get away is desirable during the first year, but the latter is not injurious if weeds or associate grasses are absent.

In the second year the plants are thoroughly established and capable of withstanding comparatively heavy grazing. The first 12 months after seeding comprise the critical period of the pasture. Plants which survive this period are usually permanent. Under systematic stocking, pastures of *P. tuberosa* and subterranean clover under favorable conditions have been found capable of maintaining relatively large numbers of livestock—upwards of four sheep per acre. Alternatively yields of 2 tons to 4 tons per acre of good quality hay are obtainable. Compared with other pasture plants, *P. tuberosa* is most prominent during the autumn and winter

months. Its development at the Waite Institute is more evenly distributed over the year than any other species except *Danthonia*. At Adelaide the grass is dormant from early January to the end of March, but in more favored areas the period of dormancy is shorter.

One of the most characteristic features of *P. tuberosa* is its drought-resistance. A second feature of importance is its capacity to persist on soils of widely varying fertility, including poor sandy types, provided the subsoil conditions are suitable. On the poorer types its yield is low so long as the fertility remains low, but its persistence enables it to take immediate advantage of increases in soil fertility resulting from the development of annual clovers, such as subterranean clover, growing in association with it. In trials conducted by the Waite Institute at various centres in South Australia, *P. tuberosa* has been the only species to persist throughout a period of four seasons. These trials have been carried out under rainfall conditions varying from 18in. to 32in. and on widely varying soil types, including the very poor podsolised types found at Kybybolite, Mount Compass, and Inman Valley. The evidence that the majority of plots established prior to 1914 are still persisting indicates a high degree of longevity. Many of these plots are unproductive owing to poor soil fertility or the absence of management, but the plants established so long ago have persisted under adverse climatic conditions, including the drought of 1914, and this evidence provides much justification for the selection of the grass as a basis with subterranean clover for pasture development under certain conditions in South Australia. Of particular interest is a small patch of *P. tuberosa* established on sandy "heath" country on the property of Mr. T. P. Bell, Tintinara, approximately 20 years ago. The soil type is considered too poor for pasture grasses generally, but supports evening primrose, and the rainfall conditions, 18in. per annum, are not sufficiently favorable for ordinary subterranean clover. The *Phalaris* plants have been continuously grazed by rabbits, but are still persisting, though their yield is low. It has also become established among uncleared heath scrub near by.

(e) Management.

The cardinal features of first-year management are (1) reduction of competition by thorough soil preparation and intermittent grazing in late winter; (2) the provision of superphosphate, 1½cwt. to 2cwts. per acre, and a suitable associate legume, such as commercial or Dwalganup early subterranean clover, 4lbs. per acre; (3) sowing before mid-winter, with due regard to the provision of surface conditions suitable for germination (*vide* p. 414); and (4) the use of good, viable seed of true perennial *P. tuberosa* at a seed rate of 1lb. to 4lbs. per acre.

Faulty management during the year of establishment may result in total failure or permanent injury to the stand.

Management during the second and subsequent seasons presupposes the maintenance of fertility by annual dressings of superphosphate and reasonable clover development.

The relative values of varying forms of grazing management have yet to be worked out in practice, but the results of Richardson, Trumble, and Shapter (13) and of Cashmore (12) in this connection are very significant.

In the former paper it was suggested as a result of pot culture experiments that a system of three defoliations per annum could be expected to give better results from the point of view of productivity maintenance than more frequent defoliations. In these tests, however, cuts were made systematically at regular intervals, and where five cuts were imposed, herbage was removed during the spring-early summer period—a critical time in relation to drought-resistance and autumn regeneration.

More recent investigation carried out under field conditions by Cashmore has confirmed in general the conclusions derived from the pot culture experiments, but has further shown that *P. tuberosa* is particularly sensitive to defoliation during the spring and early summer. At this time there is a marked downward movement, of nutrients (13) which probably assist in the development of the root system during the later stages of growth and facilitate autumn regeneration. The downward movement of reserves is indicated by obvious enlargement of the basal internodes towards the end of September, several weeks before panicle exertion (heading) at Adelaide, and continues till the end of December when the plants mature. It is thus evident that defoliation between the middle or end of September and the middle or end of December is bound to restrict downward movement, thereby limiting the accumulation of reserves, and *per se* both drought-resistance and vigor of autumn regeneration. The practical outcome would therefore seem to be as follows:—(1) Grazing, preferably on an intermittent basis from autumn to spring (mid-September at the Waite Institute); (2) complete spelling from mid-spring to early or mid-summer; (3) the utilization of the final development—(a) as hay, cut at the heading or flowering stage, (b) for seed production, or (c) as mature standing herbage in the manner usually followed with “natural” pastures. Actually this procedure would fit in very conveniently with “natural” pastures of an annual character, which are invariably under-grazed during the flush period in spring, and over-grazed during the autumn period of shortage. The utilisation of *P. tuberosa* as an adjunct to natural pastures would be of particular value in supplementing the supply of feed during the late autumn and winter, and in providing hay or mature herbage superior in quality to much of the herbage produced by natural pastures. Thus the spelling of *P. tuberosa* in spring and early summer is not only readily possible owing to the abundance of natural feed at that time, but would actually prove an advantage in enabling more effective use to be made of the natural pastures, tending to lessen the wastage caused by the development of large quantities of inedible seeds and fibre.

(f) *Seed production.*

The seed production of *P. tuberosa*, whilst considerably less than that of the rye-grasses grown under similar conditions, is of a moderate order, and not poor as is popularly supposed. The reputation the grass has for low seed production is probably derived largely from its readily shedding character and uneven ripening. The yield of seed per plant is usually from 2 to 5 per cent. of the total weight, compared with 10 to 30 per cent. in the rye-grasses, but it is rare to obtain more than 100lbs. of seed per acre in practice owing to harvesting difficulties.

Capacity for seed production varies with the strain, and early flowering types are the heaviest yielders in this respect. The species is normally cross-pollinated, and it is significant that the types which flower early tend towards the erect, stemmy growth form, and the later maturing plants to a leafier, denser type, low in seed production. It has been possible, however, to isolate desirable leafy types which flower sufficiently early to permit satisfactory seed production at the Waite Institute.

Harvesting operations are beset with many difficulties, and there is room for skill and originality in avoiding loss by shedding. Two alternative methods are available:—(1) Cutting with the binder, followed by stooking and threshing; and (2) removal of the heads by means of a stripper or header harvester. Whatever method is used, modifications of the ordinary cereal machines are necessary.

The principal advantage that the binder offers is an opportunity of obtaining the maximum yield of seed. The crop should be cut when the seeds of the upper portion of the inflorescence are mature and commencing to drop. Seeds are liable to be threshed on to the canvas of the binder and deposited on the ground; hence a detachable trough placed below the rear roller of the lower canvas is advisable to retain this seed, which is usually the heaviest. Moreover, the sheaves lose

appreciable quantities of seed when ejected from the machine to the ground, and a sheaf carrier is necessary to avoid this second source of loss. At the Waite Institute, the sheaves are laid out spoke-wise on tarpaulins made from secondhand cornsacks*, and when cured are carted to a stationary stripper, power-driven, the mature inflorescences only being passed through the machine. The principal disadvantages of the binder method are the number of handlings required and consequent loss of expediency, and the liability to garner the seeds of weeds or other plants growing in association.

The combined harvester offers the most expeditious method, and this is of paramount importance in taking off appreciable areas. Furthermore, as *P. tuberosa* is generally taller than associate plants such as *Lolium* species, *Festuca myuros*, and docks (*Rumex* spp.) any implement which harvests only the heads tends to collect a clean sample. On the other hand, this method appears to yield rather less seed per acre, and unless care is taken to harvest at exactly the right stage a large proportion of green seed may be collected, resulting in low viability of the sample.

In order to secure a comparison of the seed yields obtainable using the above two methods, an acre of *P. tuberosa* at the Waite Institute was subdivided on the ABBA system into 12 plots each 1/25th acre, with "buffer" plots to allow tracks to be cut by the machines. The six "A" plots were cut with the binder at the stage described above, and the sheaves were subjected to the operations already discussed. The six "B" plots were stripped when all but the lower spikelets of the inflorescence had matured. Owing to favorable weather conditions, including an absence of hot dry weather and severe winds, comparatively little seed had shed before stripping was commenced. During the stripping process, however, appreciable quantities of seed were lost. Although the area was fed off with sheep until early September, the crop at harvest was rather more than 5ft. in height. The machine employed was a standard stripper with a maximum comb lift of 3ft. 6in. Had it been possible to raise this comb to the leafless portion immediately below the inflorescence, much choking of the machine could have been avoided and less seed lost. On the other hand the weather conditions were exceptionally favorable for the retention of seed by the inflorescences, and considerably more seed might have been lost prior to stripping.

The seed in all cases was cleaned by sieving and the use of a small blower with controlled draught. This produced an excellent sample. The results of the test, in terms of the yield of seed per acre, percentage viability and number of seeds per pound are given in the following table:—

TABLE IV.—Showing Yield of seed (Lbs. per Acre), Percentage Viability, and Number of Seeds per Pound when Harvested by (a) Cutting and Threshing, (b) Stripping.

Method of Harvesting.	Yield of Seed. (Lbs. per Acre).	Mean Viability.		Mean No. of Seeds per lb.				Wght. per Bush. (lbs.) July, 1933.
				Total.		Viable.		
		Feb., 1933.	July, 1933.	Feb., 1933.	July, 1933.	Feb., 1933.	July, 1933.	
(a) Cutting and threshing	119.73	63.9	78.7	388,017	353,822	247,943	278,458	43.6
(b) Stripping	92.37	67.3	79.0	341,304	327,746	229,698	258,919	50.4

Odds that the mean yield of seed obtained by cutting and threshing is significantly greater than that obtained by stripping—38.7 : 1.

*This method was suggested by Mr. Alan F. Wilson, of Beaconsfield, Victoria.

The yield of seed and number of seeds per pound were significantly greater in the case of the "cut and threshed" series, which produced 27.36lbs. per acre and 46,713 seeds per pound more than the "stripped" series. There was, however, no significant difference in the percentage viability of the two types of seed. It is of interest to note the improvement in viability of both lots between February and July, providing a further illustration of after-ripening in this species.

The total yield of grass was approximately 2 tons per acre. In addition to this yield the acre had carried 100 sheep for 10 days during the autumn and winter months.

E. CHARACTERS RELATING TO THE DROUGHT RESISTANCE AND PRODUCTIVITY OF *PHALARIS TUBEROSA*.

(a) *Function of the root system and basal internodes.*

The seedling plant of *P. tuberosa* produces relatively few main roots which, however, rapidly penetrate the soil to an appreciable depth. At the Waite Institute, first year penetration through a heavy subsoil clay has reached a vertical distance of 76in. (12). The roots whilst small in number are poorly branched, and sparsely occupy the surface soil during the year of establishment. This permits the free entry of weeds, and also accounts for the suppressing effect of perennial rye-grass, which tends to occupy effectively the surface layers of soil.

The basal internodes beneath the soil surface are prominent morphologically, and, together with the root system, provide a means of storage for food material which is used by the plant for the production of herbage in the following autumn. In terms of dry weight the root system was found to comprise 30 per cent. and the basal internodes 20 per cent. of the plant (13); thus approximately 50 per cent. of the total dry weight of the plant may be underground. Of the total nitrogen and phosphoric acid present in the plant at maturity, 57 per cent. of both nutrients was present in the underground portion. More nitrogen was present in the roots than in the basal internodes, whereas more phosphoric acid was contained in the basal internodes than in the root system.

Autumn regeneration takes place entirely from the basal nodes of the underground portion of the stems, which bear external buds, three or four to each tiller. The development of both stem buds and root buds during the autumn following establishment is vigorous, enabling the plants to occupy the ground effectively at an early stage under favorable conditions for growth. The established sward is of a dense turf-like nature, and when vigorous is highly resistant to the entry of annual weeds.

(b) *Water requirement and drought-resistance.*

The transpiration of *P. tuberosa* is, as Maximov has shown in many plants of a drought-enduring character, comparatively active. Expressed as the transpiration ratio the water requirement appears to be higher than that of the cereals and of Wimmera rye-grass, and slightly higher than that of perennial rye-grass.

The transpiration ratio for *P. tuberosa* was determined at the Waite Institute during 1925, 1931 and 1932. In each of these three seasons Cape barley was grown under similar conditions, and a comparison of the two plants is given in the following table.

TABLE V.—*Showing Transpiration Ratios for Barley and P. tuberosa, Waite Institute, 1925, 1931, 1932.*

	1925.	1931.	1932.
Cape barley	269	233	312
<i>Phalaris tuberosa</i>	529	527	602
<i>Phalaris tuberosa</i> with barley at 100 .	196	225	193

It would thus appear that the water requirement of *P. tuberosa* is comparatively high in relation to that of cereals; for each unit of dry matter produced *P. tuberosa* transpires approximately twice as much water as barley. It is evident therefore that the drought-resistance of this grass cannot be associated with water economy.

An important feature of *P. tuberosa* is its capacity to enter a condition resembling anabiosis, or suspended animation prior to the onset of dry conditions. In addition, the root system has been found to extend materially in penetration (12) and to increase in dry weight (13) after the flowering stage, although there is little increase in the stem development during the final period. Associated with these features is the close coincidence of the plant's life cycle with the periodicity of the Mediterranean type of climate.

The advantages of deep root penetration are threefold, enabling the nutrients of a large area of soil to be exploited, additional moisture to be gained, and more favorable temperature relations to be secured. Evidence from the Waite Institute soil temperature records shows that the temperature of the top inch of soil may vary from 32°F. to 130°F. in the Adelaide district. On the other hand, the amplitude at 2ft. is only 34°F., with a mean annual temperature of 65°F. Records obtained by Smith (14) at Davis, California, indicated similar temperature changes at 2ft. and in the surface layers, and showed that at 6ft. the mean annual temperature was also 65°F., the maximum annual amplitude 18°F., and the lag compared with surface temperatures 8 weeks. This lag indicates that when the surface soil is under extremes of temperature the subsoil at 6ft. is fairly close to the optimum for growth.

It is of interest to note that the main roots, particularly in the upper soil layers, develop a woolly covering and a corky inner cylinder, which completely insulate them from loss of water to the surface soil, which becomes hot and dry during the summer months.

Contact between the root system and the relatively cool moist layers of the deeper soil strata is apparently essential for summer persistence. If the roots are cut at 6in. below the soil surface—an operation which was performed at the Waite Institute during the 1931-32 summer—the plants fail to survive. If the entire root system is exposed to normal summer atmospheric conditions, the plants also succumb. A series of 88 single potted plants of *P. tuberosa* were treated in 11 different ways during the 1932-33 summer, using eight replications per treatment. Thirty-two plants were washed out at maturity, and the root system freed from soil. The plants were immediately stored in tins in four places, (1) in a cool store at 33-35°F., (2) in a basement at 64-72°F., (3) in a room at 58-74°F., and (4) in a glasshouse at 45-110°F. When replanted in the following autumn all plants were found to be dead. Similarly, plants allowed to remain in pots under the above four temperature conditions, with the soil just dry enough to prevent growth, failed to live throughout the summer. Finally, 24 pots were provided with artificial subsoils by removing the bottoms of the earthenware pots and allowing the roots to penetrate a quantity of ordinary soil at a favorable moisture saturation, and placed in an 8in. enamelled pot of 7 Kg. capacity. A layer of gravel 1in. in thickness was placed between the "subsoil" of the enamelled pot, and the soil of the bottomless earthenware pot, and the roots were allowed to penetrate the "subsoil" eight weeks before maturity. Pots of this series were placed under three of the various temperature conditions, none being placed in cool storage. In all cases, however, the plants died, being incapable of regeneration in the following autumn.

It appears evident that some factor in addition to moisture and temperature enters into the process of summer dormancy in *P. tuberosa*, and an explanation may be found in the oxygen relations of the root system. Provided that the plant

is in a growing condition, oxygen is necessary for root respiration. When the whole of the stem and the upper portion of the root system is in a condition of complete dormancy, however, anabiosis of the protoplasmic growing points in the deep subsoil layers can probably only be induced by a high partial pressure of carbon dioxide or by reduced oxygen supply leading to a suppression of activity. In the "subsoil" series described above, favorable conditions of aeration in the small quantity of soil used may have been responsible for the complete mortality recorded.

The nature of the subsoil would therefore appear to be of paramount importance in determining the drought-resistance of *P. tuberosa*, particularly in regard to moisture retentivity, temperature, and the exclusion of the air.

(c) *Chemical composition.*

The chemical composition of *P. tuberosa* at varying stages of growth and under different frequencies of cutting has been worked out in detail by Richardson, Trumble and Shapter (13).

The main feature is the wide variation in composition with the stage of growth of the plant. During the early vegetative stages the herbage is particularly rich in protein and minerals, but after panicle exertion the percentages of protein and minerals fall rapidly, resulting in mature herbage of comparatively low feeding value.

There is actually less nitrogen and phosphoric acid in the herbage at maturity than at an earlier growth stage. No loss of nitrogen and phosphoric acid is sustained by the plant system as a whole; downward migration to the underground portion of the plant accounts for the loss sustained by the herbage.

With respect to potash, however, a substantial and absolute loss was found to occur from all portions of the plant during the final stage of growth. This loss, which represented 27.8 per cent. of the total intake, must be regarded as a migration of potash from the plant to the soil, and may be due to diffusion from the root system at the stage when physiological activity ceases.

Under varying cutting treatments it was found that the yields of herbage, basal internodes, and roots were considerably reduced by increasing the number of cuts. Cutting five times reduced the yield of herbage by 54 per cent. and the root system by 78 per cent.

The yields of protein and phosphoric acid in the herbage were increased, however, by each treatment involving more than one cut. The maximum yield of protein, three times that of the single cut series, was obtained under five cuts; the maximum yield of phosphoric acid, 63 per cent. greater than that of the control, under two cuts.

The water requirement per unit of dry matter was not significantly different under frequent cutting from that of the single cut series, but the water required per unit of nitrogen and/or phosphoric acid was greatly reduced by increasing the number of cuts. The practical application of this, in areas of low and uncertain rainfall, is obvious, but the lessened vigor and drought-resistance of the plant arising from too frequent defoliation, particularly in the spring, must be recognised.

(d) *The relation of management to productivity, drought-resistance, and persistence.*

In the light of the evidence discussed above, effective management in the case of *P. tuberosa* would appear to be governed by a suitable compromise between intermittent grazing, aiming to produce nutrients at low water cost on the one hand, and spelling to enable sufficient root development and food storage to occur before summer on the other. A system of autumn and winter grazing, followed

by resting in late spring and early summer, such as has been already suggested (p. 414), would provide such a compromise. It is important to note that in the case of a hay cut carried out at the heading stage to ensure hay of high quality, this must be obtained to some extent at the expense of early development in the following autumn. The requirements of particular cases will determine which is most important, but it is probable that the maximum hay yield (in terms of nutrients) and the maximum autumn development cannot both be obtained under the same system of management. To ensure maximum autumn development the herbage should be allowed to dry out entirely.

At the Waite Institute the method of management adopted has been to conduct three to four grazings at intervals of approximately seven weeks between April and September, and to spell the pasture from the middle of September onwards. If hay is taken, this is cut in early November, and a fairly long stubble is left. Harvesting for seed production is carried out at the end of December, whereas if the herbage is grazed as dry feed during the summer and autumn, stock are allowed access towards the end of January.

The persistence of the grass is affected adversely by injudicious management and a decline in soil fertility, due to insufficient top-dressing with superphosphate and the absence of pasture legumes. On the other hand, the range of adaptability to both varying management and varying soil fertility is extremely wide.

Where *P. tuberosa* has been established for many years it is liable to become sod-bound as in the case of *Paspalum dilatatum*, a summer-growing grass of similar growth-form in the vegetative condition. This is due, however, as in the case of *Paspalum*, to an excess of carbohydrate reserves in relation to nitrogen, and can readily be avoided by mechanical renovation, the application of nitrogenous fertilisers accompanied by rotational grazing or by due regard to the development of associate legumes.

F. SOME AGRICULTURAL FEATURES OF *PHALARIS CANARIENSIS*, *P. MINOR*, AND *P. COERULESCENS*.

The cultivated canary grass (*P. canariensis*) has become more prominent in recent years than formerly owing to an increase in the price of imported canary seed following an increased tariff on this commodity. Canary grass may be grown over much of the wheat belt in Southern Australia, and is adapted to the methods of cultivation employed for wheat and barley. The seeds are considerably larger than those of *P. tuberosa* or *P. minor*—60,000 per pound as compared with 300,000 per pound. Twenty pounds per acre is a satisfactory seeding rate, and the yields usually obtained vary from 10bush. to 15bush. per acre. The weight of a bushel is approximately 60lbs. The seeds shed readily, but not so readily as those of *P. tuberosa* and *P. minor*. Care must be exercised in harvesting, however. The grass is of little value apart from its seed production, and is useless for pasture development.

Wild canary grass (*P. minor*) is the most widespread species of *Phalaris* in the cultivated areas of South Australia, and is found throughout the wheat belt. When grown on fertile soils under conditions of cultivation this species is capable of producing high yields of succulent herbage. *P. minor* is similar in seasonal yield and persistence to Wimmera rye-grass, but the herbage is of a more succulent nature. With Wimmera rye-grass available this species is unnecessary, and in view of the confusion it has caused and is liable to cause with *P. tuberosa*, it must be regarded as an undesirable species.

P. coerulescens is a grass with several attractive characteristics. Like *P. tuberosa* it is perennial and highly drought resistant. The growth-form is more erect, and the tillering capacity per plant is poorer, but the leaves are finer and rather more leathery in texture. Flowering and maturity are considerably earlier than in *P. tuberosa*. The water requirement is, moreover, appreciably less. It appears to be sensitive to competition, as in the case of other *Phalaris* species. Although not as productive as *P. tuberosa*, *P. coerulescens* is worthy of further trial, particularly under conditions too arid for *P. tuberosa*.

A comparison of the development and water requirement of the two perennial winter-growing species of *Phalaris* was made in pot cultures during the 1932 season. The seeds of both species were sown in boxes on April 1st, and three seedlings were planted per pot on July 13th, 1932. The plants were carried through to maturity, and the technique employed was the same as that commonly used at the Waite Institute.

The results of this investigation are shown in the following table:—

TABLE VI.—Showing the Comparative Development and Water Requirement of *Phalaris coerulescens* and *P. tuberosa* under Similar Conditions in Pot Cultures, Waite Institute, 1932.

	Date of Flowering.	Date of Maturity.	Transpiration (Kg.).	Dry Matter Production (gm.).			Transp. Ratio.
				Herbage.	Basal Internodes.	Root System.	
<i>P. coerulescens</i>	Nov. 1	Dec. 8	69.93	86.82	59.18	24.43	479
<i>P. tuberosa</i>	Nov. 22	Dec. 27	89.23	120.09	28.22	45.99	602

The flowering of each species was about three weeks later than occurred in the field owing to glasshouse conditions.

The earlier maturity of *P. coerulescens*, which closely coincides with that of the two annuals, *P. canariensis* and *P. minor*, is illustrated by these results. The quantity of herbage produced and the dry weight of the root system were both appreciably lower in *P. coerulescens* than in *P. tuberosa*. On the other hand, the development of the basal internodes was considerably greater in the former. The basal internodes, particularly the lowest, become conspicuously swollen as early as the seedling stage in *P. coerulescens*, and provide a useful means for the identification of this species in the vegetative state. The water requirement is significantly lower in *P. coerulescens*, probably as a result of its earlier maturity. Further investigation of this species is warranted.

The major taxonomic differences of these species are described by Allan and Zotov (8) and by Gardner and Meadly (15). It is not proposed to enter further into the taxonomic discussion here. Comparatively little data concerning their identification from vegetative characters has been given, however, and the following information may prove of value:—

All species of *Phalaris* appear to possess colored sap, which shows as a purple or pinkish exudation when the young shoots are cut across near the base with a sharp knife. This characteristic has not been found in any group other than the *Phalaris* genus. The leaves are usually quite glabrous, bluish green, and the leaf shoot is rolled in the bud. The principal vegetative features on which identification may be effected are included in Table VII.

TABLE VII.—Showing the Principal Vegetative and Growth Characters of Selected *Phalaris* Species.

	<i>P.</i> <i>arundinacea.</i>	<i>P.</i> <i>tuberosa.</i>	<i>P.</i> <i>coerulescens.</i>	<i>P.</i> <i>minor.</i>	<i>P.</i> <i>canariensis.</i>
Habit	Rhizomic perennial	Soboliferous or shortly rhizomic perennial	Erect soboliferous perennial	Divaricate annual	Erect annual
Incidence of growth ..	Summer	Winter	Winter	Winter	Winter
Vegetative characters—					
(a) ligule	Short	Long	Extremely long	Long	Appreciable to long
(b) ribs of leaf blade	Acute, in pairs	Almost absent	Acute	Broadly convex	Acute
(c) tillering	External	External	External	Internal	Internal
(d) basal internodes	Normal	Swollen, oval	Swollen, rounded	Normal	Normal
(e) stem and sheath colorations	Green	Green	Purple	Purple	Green
Approximate date of flowering at Adelaide	*	Early Nov.	Early Oct.	Early Oct.	Early Oct.
Seed production	Poor	Moderate	Poor to moderate	Liberal	High
Time taken for germination to commence at 20° C. (days)	4	3	1½ to 2	2½	2

* Many samples of *P. arundinacea* do not flower at Adelaide. During the 1931 and 1932 seasons a few plants have flowered in late November and in December.

Figure 7.—Representative "seeds" and outer glumes of *Phalaris* species—1. *P. canariensis*. 2. *P. minor*. 3. *P. coerulescens*. 4. *P. tuberosa* (from an improved agricultural strain). 5. *P. tuberosa* (ex Palestine). 6. *P. arundinacea*.

The "seed" and glume characters of these species are shown in Fig. 7, and the seedling characters in Fig. 8.

It is obvious that the vegetative characters normally employed, and particularly the size and shape of ligule, prominence of ribs on the leaf blades, the degree of swelling of the basal internodes, and sheath colorations are liable to vary with

the environment, but the above characters have so far been found reliable at Adelaide. To these may be added the pink root tip character for *P. minor*, which is a useful guide in the identification of seedlings.

As the distribution of *P. canariensis* is not extensive, except where specifically grown for seed, and the two perennials *P. arundinacea* and *P. coerulescens* are rarely to be found outside testing stations, the differences of importance are those between *P. tuberosa* and *P. minor*. The pink root tip character for *P. minor* has so far proved the most reliable single characteristic at the Waite Institute, but the differences in type of tillering and in permanence are important in the field.

Figure 8.—Representative seedlings of *Phalaris* species 12 weeks after seeding—
1. *P. arundinacea*. 2 and 3. *P. coerulescens*. 4 and 5. Two distinct strains of *P. tuberosa*. 6. *P. minor*.

SUMMARY AND CONCLUSIONS.

The species of the *Phalaris* group, commonly known as the canary grasses, are adapted to the agricultural areas of Southern Australia receiving liberal winter rainfall and periodic summer drought.

The most valuable form for the seeding of permanent pastures is *Phalaris tuberosa* L., as developed from material grown at Toowoomba, Queensland, towards the end of the nineteenth century. A second perennial species, *P. coerulescens* Desf., is worthy of further investigation, particularly under conditions too arid for *P. tuberosa*.

The principal features of *P. tuberosa* are its capacity for production during autumn and winter, its drought-resistance, stability, adaptability to widely varying soil types, adaptability to varying conditions of management, and its capacity to grow in association with subterranean clover.

Reasons for the restricted use of this grass in South Australia during previous years include a tendency to shed the seeds readily at maturity, a poor capacity for spreading on non-cultivated land, and an unfortunate confusion between *P.*

tuberosa and the annual *P. minor*. Furthermore, the perennial species is highly sensitive to competition, particularly from the rye-grasses, during the year of establishment.

The structure and depth of penetration of the root system are probably important in relation to both drought-resistance and susceptibility to competition during the first year.

Sustained productivity in swards of *P. tuberosa* is greatly dependent on soil fertility. A suitable associate legume and continued applications of soluble phosphate are desirable.

Low seeds rates are indicated. On well-prepared land of good fertility 4lbs. per acre of reliable seed is sufficient. On poor soils 2lbs. per acre or less may be sown in conjunction with a suitable pasture legume.

Intermittent grazing from autumn to mid-spring, followed by spelling until early or mid-summer, and the utilisation of the final development as hay, for seed production, or as mature standing herbage, appears to be an effective method of managing *P. tuberosa*. The accumulation of basal reserves in early summer is of paramount importance for regeneration during the following autumn.

Seed production is of the order of 30lbs. to 150lbs. per acre. Cutting and threshing gave a significantly higher yield of clean seed than stripping. The relative merits of the two methods of harvesting are discussed.

Seed which has matured under relatively cool moist conditions may require a period of after-ripening.

The drought resistance of *P. tuberosa* is not associated with a low transpiration rate, but appears to be governed by its deep rooting habit and a capacity to enter a condition of anabiosis, or suspended animation, prior to the onset of dry conditions. Associated with these features is the close coincidence of the plant's life cycle with the periodicity of the Mediterranean type of climate.

Some agricultural features of a number of allied forms are discussed.

ACKNOWLEDGMENTS.

The author desires to express his thanks to Mr. A. B. Cashmore, B.Sc., for his co-operation and assistance in breeding work now in progress, and from which much information on the agronomic side has been obtained. Thanks are also due to Miss R. Pulford, who carried out the germination tests, to Messrs. D. L. Parker and E. J. Leaney, who have rendered assistance in the pot culture house, the laboratory, and the field, and to Mr. A. D. Cocks, who made the various photographs.

DAIRY INDUSTRY PRICES.

ROYAL COMMISSION REPORT TO HIS EXCELLENCY THE GOVERNOR.

[A Royal Commission, consisting of Messrs. W. J. Dawkins (Chairman), Professor A. J. Perkins, and J. W. Wainwright, was appointed in January to inquire into and report upon the disparity between the prices paid by the consumer for dairy produce, the London parities of dairy produce, and the prices received by dairymen for milk and cream, the cause of such disparities, and the remedies therefor. The report is dated October 20th, 1933, and portion of it is quoted below. It is proposed to complete the report in subsequent issues.]

SCOPE FOR THE INQUIRY.

The inquiry has as much as possible been confined to matters relevant under the terms of reference, namely, "To inquire into and report upon the disparity between the prices paid by the consumer for dairy produce, the London parities of dairy produce, and the prices received by dairymen of South Australia for milk and cream; the causes of such disparities, and the remedies therefor." Subsequently to the receipt of these terms of reference, a suggested Bill for the Control of the Milk Supply of the Metropolitan Area was also submitted by the Honorable the Chief Secretary for examination and report.

In the course of these inquiries, several minor questions came under notice, and although some of these questions could not, perhaps, be strictly brought within the terms of reference, when deemed to be of sufficient importance to the inquiry to warrant investigation, they have been dealt with accordingly.

SOURCE OF THE EVIDENCE.

The evidence upon which this report has been based was secured from verbal statements, correspondence, printed reports, commercial books and statements, and visits of inspection.

Evidence was tendered by individual dairymen and milk vendors, by associations of vendors and producers, the Metropolitan County Board, the Central Board of Health, butter and cheese factory proprietors and officials, officers of the Department of Agriculture, and by other interested parties, who came forward voluntarily.

Evidence was also taken in Melbourne from local controlling authorities, milk vendors and distributors, factory proprietors, &c., and in the course of inspection of the premises of milk vendors and dairy farmers supplying the metropolitan area of Melbourne.

Your Commissioners were supplied with numerous reports and statements from the sister States, Commonwealth Departments, New Zealand, and England; and for these they desire to express their indebtedness. Outstanding among these publications is probably the Report of the Commission for the Re-organisation of Milk, issued in England in January, 1933.

Subsequent to their visit to Melbourne, your Commissioners inspected several dairies and shops licensed to sell milk within the metropolitan area, and some dairies outside the metropolitan area, with a view to testing the value of evidence submitted by several witnesses as to the sanitary conditions under which milk, cream, and butter were being handled and sold in Adelaide.

"WATTLE" Binder Twine

MADE IN SOUTH AUSTRALIA.

"Good Twine Saves Time."

Farmers who insist upon a **QUALITY** Twine (keeping one eye on economy) should order "Wattle" brand this season.

"Wattle" brand has established a reputation for quality. Its unusual strength ensures freedom from breakages, it runs freely and evenly, thereby saving time and money.

SUPPLIES OBTAINABLE FROM ALL DISTRIBUTORS.

In order to confirm or correct their personal views on the matter, it was deemed wise to secure those of a competent outside observer, and accordingly the services of Mr. David Rutledge, Senior Dairy Supervisor of the Victorian Department of Agriculture, were obtained, and he was asked to inspect and report upon some of the dairies supplying milk to the metropolitan area.

THE RELATIONSHIP OF DAIRY PRODUCTS TO PUBLIC HEALTH.

The draft Bill for the control of milk in the metropolitan area submitted for consideration and report, provided that such control, including sanitary supervision, should be exercised by a board consisting in the main of nominees of dairy-men, distributors, and vendors. Hence, it follows that should the Bill be enacted questions of hygiene on the farm, in the dairy, or on the milk cart, upon which the well-being of the community might be dependent, would be left in the inadequately trained hands of specially interested parties. Inquiries into the probable results of these proposals were therefore made.

All the competent authorities that your Commissioners have consulted on the subject appear to be of one opinion as to the danger to public health of careless or unhygienic handling of milk and dairy produce generally. It is recognised that the conditions under which milk is usually produced and handled render it specially liable to bacterial and organic contamination; and that its natural composition and relatively high initial temperature make of it an ideal medium for rapid bacterial growth. Moreover, milk is the natural foodstuff of infants, and is often fed to them in the raw state. Hence, milk—more than any other human foodstuff—should be adequately protected from contamination at all stages. In this connection, the Chairman of the Board of Health (Dr. A. R. Southwood) has been good enough to prepare a statement, which sets out very clearly the dangers to which the community is exposed by the careless or unhygienic handling of milk, and to which special attention is directed.

The conclusions of Dr. Southwood's statement may be summarised as follows:—

1. That the following diseases are frequently spread by milk:—Tuberculosis, typhoid fever, scarlet fever, diphtheria, septic sore throat, abortus fever, diarrhoeal and dysentery diseases of infants and adults.

2. That infection of milk by organisms responsible for these diseases may arise from contact with human beings handling the milk, or from cows.

3. That in America 8.3 per cent., and in England 9.5 per cent. of samples of milk examined have been found to be tubercle-infected.

4. That cream, butter, buttermilk, ice cream, sour milk, fresh cheese, and other milk products may convey all the infections contained in the original milk from which they were prepared.

5. That milk products are frequently made from the left-over milk, or milk that is otherwise unsaleable.

6. That adequate pasteurisation is the simplest, cheapest, least objectionable, and most trustworthy method of rendering milk safe.

7. But that pasteurisation is not a substitute for efficient inspection.

8. That inspection should give cleaner and better, but not necessarily safe milk; that adequate pasteurisation completes the work of inspection by eliminating the dangers that the latter cannot see.

9. That bovine tuberculosis should be dealt with by regular tuberculin testing of cows, by the building up of tubercle-free herds, by routine clinical examination of cattle by competent veterinary surgeons, by the testing of milk by microscopic and biological methods, and by the education of cow-keepers in the prevention of bovine infection.

For the above and other reasons, and having in mind evidence given as to the unsanitary conditions under which cows are frequently housed and milked, the carelessness with which milk is frequently handled in shops or on carts, and the unhygienic fashion in which milk is usually ladled out at back doors, your Commissioners have no hesitation in affirming that to place the control of the milk supply of a large city in the hands of specially interested parties would not be in the best interests of the community.

SUBDIVISIONS OF REPORT.

In South Australia the dairy products said to be subject to disparity in prices can be limited to:—

1. Whole milk;
2. Butter; and
3. Cheese.

The manufacture of cheese is more or less localised in the South-East, and as no complaints were received concerning cheese prices, this report deals with whole milk and butter only.

1. WHOLE MILK.

In the report of the Re-organisation Commission for Milk, 1933, England, it is stated that the main objects in view have been as follows:—

- (a) The strengthening of the position of producers by enabling them to negotiate as a solid body with one voice and with adequate information, and by ensuring that negotiated agreements are universally observed.
- (b) The prevention of undercutting of the liquid market, and the provision of satisfactory arrangements for the sale of milk for manufacture.
- (c) The improvement of the quality of the milk supply.
- (d) The stimulation of the demand for milk for liquid consumption.
- (e) The recognition of the service rendered by producers who cater primarily for the liquid-milk market.
- (f) The development of the manufacture of milk products; and
- (g) The co-ordination of the efforts of all concerned—producers, distributors, and manufacturers—to secure prosperity for the whole milk industry of the country, with adequate safeguards for the interests of the consuming public.

The English Commission, after a lengthy examination of the position, submitted comprehensive recommendations for the re-organisation of the milk supply of England and Wales. Your Commissioners have had to take into consideration the incidence of local conditions, and whilst their recommendations are less far-reaching than those of the English Commission, they have been very largely based upon the same underlying principles.

A. THE METROPOLITAN MILK SUPPLY.

The milk supply of the Adelaide metropolitan area is derived partly from the metropolitan area itself and partly from adjoining country districts. The main outside sources of supply lie between Adelaide and Gawler, in the neighborhood of Mount Barker and Woodside, the Mount Lofty Ranges, the Meadows district, Myponga, and adjoining the River Murray, from Tailem Bend to Mannum.

During the past five or six years there has been a marked increase in the number of cows kept within the metropolitan area. The latter have risen from 3,900 to 5,800 head, an increase of nearly 50 per cent. This increase has naturally led to corresponding decrease in the quantity of milk previously supplied by country districts.

Nevertheless, the milk supply from the metropolitan area is very far from constant from one end of the year to the other. Normally, maximum supplies are available during the months of September, October, and November, whilst minimum supplies usually occur towards the end of summer and in early winter. These limits, however, vary considerably with the character of the seasons, which may be early or late, dry or wet, and with the price of fodders, which may have the effect of extending or restricting the period of maximum supplies. In this connection the low prices recently obtaining for hay, bran, pollard, &c., may be said to have been partly responsible for the increase in the number of cows kept within the metropolitan area.

It follows that the call on country districts for milk will vary according as metropolitan supplies rise or fall. At times it represents considerably more than 50 per cent. of metropolitan requirements; at times it falls below 50 per cent.

It is held by some that this more or less haphazard arrangement is all to the advantage of the metropolitan supplier, but to the disadvantage of the country supplier, who is called upon to meet the former's deficiencies, which vary within very wide limits from year to year. It is argued that country supplies should be based upon definite yearly contracts, involving approximately equal monthly supplies from one end of the year to the other.

B. SUPERVISION AND CONTROL.

The supervision and control of dairy farms, milk vendors, and milk shops is carried out under powers given by the Food and Drugs Act, 1908, on the one hand, and the Dairy Industry Act, 1928, on the other. Under this arrangement several authorities may hold jurisdiction over milk in the various stages of its production and distribution, namely:—

1. The Metropolitan County Board has complete control within confines of the Metropolitan County District.

2. The Department of Agriculture is responsible for every dairy farm outside the metropolitan area which supplies milk in bulk to any factory or milk vendor, whether for wholesale or retail trade, or the milk from which is used in manufacturing dairy produce.

3. The supervision of farms supplying both the metropolitan area and retailing milk in the locality is in the hands of the Local Board of Health, when the latter functions; and, if not, in those of the Central Board of Health. Hence, under existing arrangements, 50 per cent. or thereabouts of the milk intended for metropolitan consumption does not come under the control of the Metropolitan County Board until it has crossed the borders of the metropolitan area.

It appears to-day to be a recognised principle in all progressive countries that the authority controlling the milk supply of large centres of population should be in complete control from the farm to the consumer. Hence, the existing divided control in the metropolitan area of Adelaide makes it very difficult to protect consumers effectively from the lurking dangers of contaminated milk. Doubtless, when the legislation at present in force came to be adopted, it was not realised at the time how far afield the metropolitan area would eventually have to seek its milk; but remedial legislation on the subject appears to have been long overdue.

C. COSTS OF DISTRIBUTION OF MILK.

The price which could be paid to the producer of milk is very largely governed by distribution costs incurred between the premises of the producer and those of the consumer, and accordingly, special attention has been paid to the question, and much information has been collected on the subject.

Whole milk for human consumption is at the present time being purchased at city treatment plants at 6d. to 8d. per gallon. This milk is subsequently sold to vendors at 8d. to 10d. per gallon, and by the latter to domestic consumers at 16d. to 24d. per gallon. The shop prices for this milk vary from 1s. to 1s. 8d. per gallon.

Transport costs from dairy farm to the city vary with distances, and appear to range up to 2d. per gallon. The handling and treatment of this milk at the large depots costs from 1½d. to 2d. per gallon, and up to this point there appears to be little scope for reduction in costs. Present costs of distribution incurred by milk vendors in supplying domestic consumers are approximately between 8d. to 14d. per gallon, with a probable average of 1s., contrasted with which the producer receives as low as 4d. to 5d. per gallon. It is at this point—the final distribution costs of milk vendors—that economies that could lead to improvement in prices paid to producers seem feasible.

1. *The Morning Milk Round.*—The evidence of all milk vendors tends to show that, apart from a few exceptional cases, there has been very considerable reduction in the quantity of milk delivered per individual round during the past few years. The reduction of a 30gall. to 40gall. round to 20galls. and less may be taken to be typical of what has taken place in most cases. Obviously this reduction in the amount of milk delivered per individual round has led to corresponding increases in costs per gallon of milk delivered; and equally obviously increases in costs of delivery per gallon have led to reduction in prices that could otherwise have been paid to producers, without raising or lowering prices paid by consumers. The total costs involved in calling upon customers on the morning round vary from 1d. to 1½d. per call. Including all operations, such as preparation, washing, grooming, calling, &c., the time so occupied is approximately two to three minutes per individual call.

The heavy reduction in the quantity of milk delivered per individual round is principally attributable to the intensive competition of new vendors, who, for various reasons, have been attracted into the trade within recent years. Figures supplied

by the Metropolitan County Board indicate that since 1928-29 milk vendors within the metropolitan area have risen from about 700 to about 950; and shops licensed to sell milk, from 187 to 366. The amount of milk delivered daily for home consumption within the metropolitan area is in the neighborhood of 13,000 to 14,000 gallons, and the number of vendors and shops participating in this delivery is 950 and 360 respectively. The average is, therefore, not much more than 10 galls. per distributing agency.

Attention is drawn to the fact that figures supplied by the Victorian Department of Agriculture show that, on a population basis, Adelaide has at present four times more licensed milk vendors than Melbourne.

Your Commissioners, after careful inquiry into the matter, are very definitely of the opinion that it is both possible and practicable to bring about important reductions in existing costs of delivering milk for home consumption in the Adelaide metropolitan area, and that, under efficient control of the milk supply, such reductions should ensure to the milk producer his fair share of accruing benefits. In this connection various proposals have been urged upon the Commission by interested parties, and all of these have received careful consideration. Your Commissioners do not, however, think it necessary to review them *seriatim*, but prefer confining themselves to recommendations that appear to be practicable.

2. *Reduction in Costs of Delivery of Milk for Domestic Consumption.*—Economies of approximately £40,000 per annum could be realised in costs of delivery of milk to home consumers if the following practices were adopted:—

(a) By making it possible that the daily rounds of milkmen should extend over smaller areas than at present; and

(b) By abolishing the afternoon delivery of milk.

(a) *Limiting the Rounds of Milkmen to Smaller Areas.*—In the above connection there are the conflicting interests of two parties to be taken into consideration—the interests of consumers and those of vendors. Generally, in the matter of both quality and price, consumers may be said to be sufficiently protected by the operation of trade competition, supported by adequate supervision. Hence, it follows that it is to the interest of both consumers and producers that healthy competition, coupled with adequate supervision, should be restored in the milk trade of the metropolitan area, and towards this end the reduction in the present number of licensed vendors by one-quarter or one-third appears desirable. Concurrently, adequate pressure should be brought to bear upon the balance of vendors to handle milk under the most hygienic conditions possible.

Consideration has been given to the suggestion that each vendor's licence should limit his field of operation to a well-defined area; or, alternatively, that the metropolitan area should be "zoned" into a number of restricted areas, within each of which a limited number of vendors would be allowed to operate. Neither of these proposals can be recommended, as it is considered undesirable that the natural wish of the householder to select his own milkman should be unduly limited by the licensing authority. But, apart from this aspect, the method of fixing definite boundaries between adjoining areas offers serious difficulties in application.

The desired results could best be secured by limiting the number of licensed vendors and cowkeepers within the metropolitan area to numbers which can be shown to be adequate for the efficient economical supply of milk; but all existing holders of licences under the Metropolitan County Board have certain vested rights which should not be overlooked. Hence, it is recommended that:—

(1.) Early opportunity be taken to announce publicly that in the event of re-organisation in control of milk consumed within the metropolitan area, all vendors' licences in force at the time of the issue of this report will and shall be recognised; but that all licences issued subsequently to such date shall not be recognised.

(II.) The licensing authority shall take into consideration the advisability of increasing the value of licensing fees, and that in the matter of vendors, licence fees should be based upon the number of carts used.

(III.) The premises of all cowkeepers, shops, and vendors operating within the metropolitan area, together with their methods of delivery, shall be carefully scrutinised, and that all those failing to come up to prescribed standards of sanitation and hygiene shall be given reasonable time to comply with the regulations, and that failure to do so shall lead to definite cancellation of the licence.

(IV.) Both vendors and premises shall be separately licensed; and no transfer of licences shall be recognised unless authorised by the licensing authority.

(V.) The licensing authority should be given statutory power to decline to issue licences if it considered that it is not in the public interest to do so.

In the past the practice of buying out redundant vendors has apparently been availed of to some advantage in limiting the number of vendors to the requirements of the community. Latterly, however, the pressure of the economic position has been such, and the numbers of redundant vendors so great, that no vendor, however well established, could afford to buy out any of his competitors; and should he have been foolish enough to make the attempt, a new crop of competitors would have sprung up on the morrow; but if existing licence holders were given the assurance that no new licences would be issued for a definite period of time, or only until such time as, in the opinion of the licensing authority, the requirements of the metropolitan area rendered necessary the issue of additional licences, then well-established vendors would gradually buy out redundant vendors, and progressively bring down the number to the requirements of the business. In addition, when individual rounds extended over too wide an area, owners would in most cases exchange portion of their rounds with adjoining vendors. This would have the effect of consolidating individual rounds, and lead to considerable decrease in costs of distribution.

Hence, it is anticipated that reduction of licences on the lines indicated above should lead to a gradual solution of the present difficult position without inflicting any injustice upon persons now employed in the industry, or providing a fund for compensation payments.

(b) *Abolition of the Afternoon Delivery.*—At present the afternoon delivery of milk in the metropolitan area is confined to between 20 per cent. to 30 per cent. of customers served in the morning, and then only on ordinary week days. Very little afternoon milk is delivered on Saturdays, Sundays, or public holidays.

The main objection to the afternoon delivery is that it adds very considerably to costs of distribution. This point may be illustrated in the following way:—In the first place, if milk at present delivered in the afternoon were added to the usual morning delivery it would have the effect of reducing proportionately the costs per gallon of the morning delivery. Secondly, the quantity of milk distributed on the afternoon round is so small that in the great majority of cases it would be questionable whether the amount received for milk in the afternoon were even equal to costs of delivery. In other words, afternoon milk may be said to be generally given away, with at times something thrown in. In one instance examined by your Commissioners the actual costs of calling exceeded 3d. per customer, whereas the amount received per afternoon customer was actually less than 3d. It follows that the milk delivered in the afternoon did not even pay the costs of calling on customers.

The fact that so limited a number of householders take advantage of the afternoon delivery seems to show that in rare instances only can this second delivery be considered necessary. Moreover, the requirements of those who cannot do without afternoon milk can easily be met by the numerous shops and dairies scattered

over the metropolitan area, which sell milk at any time of the day. It is true that the abolition of the afternoon delivery may add to the difficulties of householders who are not accustomed to keep milk for any length of time, particularly in summer. Strict cleanliness and judicious scalding can, however, overcome all these difficulties. Moreover, the absence of an afternoon delivery will compel vendors themselves to adopt more hygienic methods than are at present in vogue. The vendor whose milk will not keep will lose his customers.

It is pointed out that even Broken Hill, with its hot, dusty conditions, had recently done away with the afternoon delivery, and had it not been for the existing intensive competition within the metropolitan area, it is probable that a similar course would have been adopted voluntarily in Adelaide.

The afternoon delivery of milk adds considerably to the difficulties and costs of the dairying industry, inflicts unnecessary labor upon a set of people who have already to work very long hours, and in present circumstances helps to make of it a "sweated industry." Hence, it is recommended that licensed vendors be prohibited from delivering afternoon milk to domestic consumers of the metropolitan area, except for such cases as are shown to be necessary. This reform is advocated on the same principle as the 6 o'clock closing of shops.

D. RE-ADJUSTMENTS IN THE MILK INDUSTRY.

In the paragraphs that precede an attempt has been made to show the extent to which economies are possible in present costs of delivery of milk for domestic purposes; but it is certain that producers will not benefit from these economies so long as the metropolitan area remains open to the uncontrolled competition of country surplus milk. At the present time milk is being distributed within the metropolitan area at the rate of 13,000galls. to 14,000galls. per day; that is to say, at the rate of about 5,000,000galls. per annum, or 10 per cent. of a total State production of 50,000,000galls., and it is safe to say that the metropolitan area is within easy marketable reach of four to five times its normal milk requirements. This surplus milk usually finds an outlet as butter or cheese, but latterly at deplorably low prices, namely, 4d. to 5d. per gallon. In the circumstances, it is inevitable that any conditions that lead to temporary improvement in the financial returns of metropolitan cowkeepers and country suppliers should have the following tendencies:—

(a) Increase in number of cows milked within the metropolitan area.

(b) More intensive competition of surplus country milk.

And the general consequence of these two tendencies would be that in a very short while the price realised by country suppliers would be very little above current butterfat prices, and that realised by metropolitan cowkeepers would be butterfat prices plus mean cost of delivery and treatment of country milk in Adelaide.

The position may be illustrated as follows:—

Let us suppose that the price to the consumer is 3d. a pint, or 2s. a gallon, and that as a result of the economies suggested the costs of delivery are reduced from an average of 1s. to 8d. per gallon. In the latter case the metropolitan cowkeeper who distributed his own milk would realise 1s. 4d. per gallon at his dairy.

The country supplier, on the other hand, with freight at 2d. and treatment at 2d., would realise 1s. a gallon on the farm.

Prices such as these would immediately attract the competition of free-lance dairymen, and within a very short period of time the country supplier would be back to 5d., the metropolitan cowkeeper to 9d., and the consumer to 1½d. a pint.

Adjustment of prices is best left to the free play of competition, unless it can be shown that unregulated competition results in conditions that are prejudicial to the welfare of the community.

The evidence given by witnesses shows definitely that unsatisfactory conditions exist in the milk supply of the metropolitan area, and prevalent insanitary methods attaching to producing, handling, and delivering milk, not only justify but render advisable early legislation to establish better control in the interests of producers, vendors, consumers, and the dairy industry generally. The prime objective in this connection should be that the supply of milk to the metropolitan area should be adequate in quantity and unimpeachable in quality, and that the retail price thereof should be as low as possible. In other words, the interests of consumers must take precedence of those of distributors and vendors, and even of the dairying industry generally. There has been no lack of metropolitan milk in the past; nor is there reason to anticipate shortage in the future; and all that need be said under this head is that restrictive measures of the future should be so controlled as not to affect the adequacy of the metropolitan supplies. Improvement in standards of quality, on the other hand, will necessarily imply more vigorous enforcement of measures of hygiene and sanitation upon producers, distributors, and vendors alike; but these measures cannot be adequately enforced until those who are reasonably efficient can obtain adequate remuneration for the production, distribution, or delivery of milk of adequate quality; and, unfortunately, adequate remuneration cannot be obtained until such time as competition in supply has been regulated in accordance with the principles outlined herein.

(To be continued.)

(In the next instalment the Commission's report will deal with the claims of householders for a higher unit value, types of milk for human consumption, control of prices, and quality in milk.)

THE GRENADIER WEAVER.

The South Australian Ornithological Association has drawn attention to the escape from captivity of the Grenadier Weaver (*Pyromelana orix*). This bird is an imported finch from Southern Africa, and has been observed in South Australia at Wood's Point, Paradise, and McLaren Flat. At the former locality the birds were noticed by Mr. H. W. Morphett about four years ago, and since then Mr. Morphett has reported that they feed on wild oats growing on banks of a drain in the reclaimed flats. Dr. A. M. Morgan, who paid a visit to Wood's Point, was informed that the birds disappeared in winter, but he points out that *as the males, after the nesting season, change their bright plumage to that of the female, they might easily have been mistaken for sparrows when in that state.* In their native land they inhabit swampy country, and do much damage to grain crops, and Dr. Morgan states that judging by the business-like way in which he saw them stripping the wild oats at Wood's Point, one can imagine what a flock would do in a wheat crop, and it seems likely, unless early steps are taken to eradicate them, that we will soon be cursed with another imported pest.

The colored plate opposite gives a description of the male bird in its bright plumage, at this time of the year, after the mating season. In "Foreign Finches in Captivity," A. G. Butler states that the adult male in breeding plumage varies according to age from orange to vermilion, the mantle cinnabar red. As with the allied species the feathers of the neck can be swelled out into a sort of ruff; the forehead, the face (including the eye and ear-coverts), and the front of the throat black; the chest and abdomen black; upper wing-coverts fiery cinnabar red, quills brown, with blackish centres; thighs, axillaries, and under wing-coverts, yellowish brown, quills below pale brown with paler inner web. Length, 4-8/10ths inches. Beak black with browner cutting edges; legs brown; iris dark amber brown. *In winter the male plumage nearly resembles the female, but he is slightly larger and darker in tone.*

The female is described as tawny brown with black shaft-streaks, narrower on the head; wing and tail feathers dark brown with pale tawny edges; a distinct yellowish eyebrow streak; under parts paler than the upper, with narrow black streaks, broadest on the sides and flanks; centre of body below yellowish; quills below dusky, and yellowish inner web. Length, 4-7/10ths inches. Beak reddish horn-brown, the lower mandible paler; legs brown; iris ashy brown.

In Southern Africa the distribution of these birds appears to be confined to narrow limits. They breed among the reeds growing in rivers, supporting the nests on three or four stems. In the winter they congregate in flocks, and do much damage to the grain fields in the neighborhood of the nesting places, but never stray away from that locality excepting when they may occasionally be driven from a district by drought or want of food. The nests are constructed of grasses, domed with a side entrance, about 4ft. or 5ft. from the ground level, and at the water's edge. The nests contain four to five eggs of a pure light-blue color, unspotted.

The behaviour of the male bird in nesting-time is described as being absolutely of such a character as to mock all attempt at description. Dr. Reichenow states:—"One constantly sees the male puff itself out and dance in order to exhibit the full beauty of its magnificent plumage to the plain, modest female clothed in grey. I believe there are no other birds so coquettish as the forms of this Weaver. The coquetry is habitual with them, amounting as one may say to folly; they even waltz when they are not observed by the female, and appear to take the greatest delight in themselves."

Supplement to the "Journal of Agriculture."]

GRENADIER WEAVER, OR "RED BISHOP" (*Pyromelana orix*).

An introduced Finch which may become a serious menace to grain crops in South Australia.

PASTURE IMPROVEMENT EXPERIMENTS IN SOUTH AUSTRALIA.

[By R. C. SCOTT, Supervisor of Experimental Work.]

The pasture experiments conducted by the South Australian Committee of the Australian Dairy Council have, in a number of cases, been in progress for sufficient length of time to allow for the expression of fairly definite conclusions.

However, the work of the pasture seed trials is only in its infancy, and selections of the most promising strains will be made during the coming summer.

The season, generally, has been favorable to the growth of established pastures, but the plants in areas seeded this season have made relatively slow growth. This is due to the cold and dry conditions experienced during the month of June, but as the germination was satisfactory these plants should make good headway with the advent of warmer weather.

The experiments are in progress over a wide range of agricultural conditions, and extend from low rainfall country (16-18in.) in the Northern and Lakes districts to much wetter areas in the Adelaide Hills, South-East, and Southern Eyre's Peninsula districts. In addition, tests with pasture varieties are being conducted on irrigated land at Long Flat.

A brief progress report of the experiments, demonstrations, and grass seed trials is as follows:—

NORTHERN DISTRICTS.

(Gladstone, Saddleworth, Eudunda, and Greenock).

In this area Greenock receives rather higher annual rainfall than the remaining centres, but in all cases the soil conditions are similar. The land is of the red-brown earth class, of good fertility, and capable of carrying heavy cereal crops.

The experiment consists of demonstrations with pasture varieties, and of these easily the most promising are Wimmera Rye Grass and Early Subterranean Clover. *Phalaris tuberosa* has proved fairly drought-resistant, making rapid growth in early autumn.

At Greenock the rainfall is sufficient to permit certified Perennial Rye Grass to persist, and when sown as a mixture with Early Subterranean Clover, a good palatable pasture stand has resulted.

ADELAIDE HILLS DISTRICT.

(Eden Valley, Mount Pleasant, Mount Barker, Bugle Ranges, Meadows, Willunga, and Myponga).

The soil conditions throughout the Adelaide Hills vary considerably, and extend from poor, hungry sands to rich black flats. The tests being conducted include both these types, and consist of pasture variety, pasture mixture, and manurial trials. The result of the experiments dealing with pastures indicates that on the better class lands Perennial Rye Grass and White Clover make the best pasture mixture. On the other hand, where the soil tends to become relatively dry in the summer, or is of lighter texture, Subterranean Clover must replace the White Clover. In the same way, wherever summer conditions render it difficult for a perennial plant to persist, the Perennial Rye Grass must be replaced by Wimmera Rye Grass.

Another very satisfactory mixture consists of *Phalaris tuberosa* and Subterranean Clover. In this connection most success has been attained by sowing the *Phalaris* alone in the first season, and in the following year adding the Subterranean Clover.

It would appear that the weak growth that *Phalaris* makes shortly after germination renders it liable to be crowded out by either weeds in dirty ground or other pasture varieties, if a mixture is seeded.

It is as yet too early to comment upon the manurial trials, except to report that considerably increased growth has followed the applications of sulphate of ammonia, but whether this additional feed has been economically obtained can only be decided when sufficient grazing data is available.

The same remarks apply to applications of agricultural lime made on the wet, sour lands of Meadows, where at the present time such dressings have led to much improved pastures.

EYRE'S PENINSULA.

(Warunda).

Warunda is situated in the higher rainfall area on Southern Eyre's Peninsula, and is essentially pasture country rather than cereal growing land.

The experiments simply consist of pasture variety trials, each fodder being planted alone in a separate plot. As the work was only commenced this season, no remarks are possible, and it remains to be proved whether the permanent plants will carry through the summer, or whether we will have to confine ourselves to the annual types.

LAKES DISTRICT.

(Meningie and Narrung).

The soil conditions in this district are rather different to those in the other areas, where experiments are being conducted. On the whole, the soil is of a red, sandy nature, on which lucerne grows fairly well without irrigation, whilst the flats are made up of heavy black land which, when not well drained, are rather salty. The experiments include pasture variety trials, and an investigation into the best method of handling the lucerne pasture sown on the land.

Wimmera Rye Grass and Early Subterranean Clover have shown the most promise as winter fodders, the latter in particular appearing very valuable for these conditions.

In connection with the treatment of lucerne, most abundant growth has followed light winter tillage with which is associated a top dressing of 10 lb. of superphosphate per acre. On the other hand, tillage without manure has given better results than manure without tillage.

SOUTH-EASTERN DISTRICT.

(Mount Gambier and Hatherleigh).

On the well-drained, fertile soils of Mount Gambier most pasture varieties make strong growth, but in these experiments the best appear to be Perennial Rye Grass, White Clover, *Phalaris tuberosa*, and Subterranean Clover. At Hatherleigh the soil is of the black, sea-mud type, and in our experience no fodders can approach Perennial Rye Grass and Strawberry Clover for this class of country.

IRRIGATION AREA.

(Long Flat).

Pasture varieties have been planted this season on the reclaimed irrigation area at Long Flat. In all cases good germination has been secured, and at present all varieties are making satisfactory growth.

PASTURE SEED TRIALS.

The following report has been submitted by Mr. L. J. Cook, Manager of the Kybyholite Experimental Farm, who is in charge of this work:—

The bulk of the plots of grass strains have withstood the winter conditions of July and August well. Much cold weather has been experienced, rainfall during June and July being exceptionally light, but average falls have been received during August.

The health of grass plants during the period has been very good, there being no noticeable deaths, and the "browning off" has only been slight. Perennial Rye Grass strains suffered more in this respect than *Phalaris tuberosa*, but they recovered well during August.

Following the June grazing, plots made comparatively good winter growth, the *Phalaris* strains making substantial headway.

During the last half of July a careful examination of this winter growth of all strains was made, and selected plants pegged. Amongst perennial Ryes particular attention was paid to healthiness, any plants with a tendency to "brown off" being passed by. Principally, plants with abundant leaf development and close growing crowns were selected. Some with spreading habit of growth and others with more erect growths were marked. A few of the more open types, with more stemmy growth, were noted, with a view to comparison in later seasons.

Short, dump pegs were cut, painted white, and numbered. These have been driven alongside the selected plants, and notes on approximately 120 individual plants recorded.

It is anticipated to collect seed from some of these selections, whilst others will be watched mainly for comparative purposes.

Of the *Phalaris tuberosa* strains, four are showing better than the others; two of those from the Sewage Farm have shown very prolific leaf growth during the winter. Also, the Mount Crawford strain has shown above the average, as well as our local strain of eight seasons' duration, although the plants of the latter show more open in the crown.

It is anticipated to collect seed from these strains during the coming summer, and plant out in isolated plots next season. A small area will be fallowed this spring, and prepared for the sowing of these next autumn.

During August the whole of the plots have been subjected to a good grazing to check the growth of annual weeds, and to maintain the grass species under good pasture conditions.

The annual Rye Grass strains sown this season have made satisfactory winter growth. Two of the seven strains have made quite superior leaf development, while others show rather a spindly and stemmy nature.

The clovers and grasses sown in small trial plots this year have, with a few exceptions, germinated and established well.

DEPENDABILITY.

There are few people who cannot recall some instance where a widow, left sole Executrix, has been badly advised and lost all that she had—where the man whom everyone trusted, speculated with the moneys placed in his care and was unable to make restitution—or where the fortunes of a family have been wrecked by the absconding of a trusted friend.

GRADING FARMERS' WOOL.

[By C. A. GODDARD.]

Grading of primary products is one of the most important factors in orderly marketing. In South Australia special attention is given to the grading of butter, dried fruits, and other products, yet a large percentage of the wool produced in the farming areas is sent to market ungraded, and the loss to the producer is tremendous.

It has been estimated that 50,000 bales of farmers' wool were marketed in Adelaide last season ungraded. To appreciate the loss involved it is necessary to know that there are two great sections in the wool textile trade, each requiring different types of wool for economic manufacture. *Firstly*, the worsted trade, which uses only wools that can be economically combed. *Secondly*, the woollen trade, which specialises in short carding sorts. The difference in the limit value of these types is often very wide, and as each type is usually found in the same fleece the importance of grading can be realised. When the wool is graded each type will bring its true value, and the best average price will be obtained by the grower. When the types are marketed together neither section of the trade can purchase them to their own or the grower's benefit. What really happens is that the sorters buy them at a price that will enable them to sort and sell at a profit; these people are really dealers.

It is impossible to estimate accurately the loss due to lack of grading, because the ups and down of a public auction have to be contended with. But after conferring with wool experts closely associated with the industry, I have no hesitation in stating that the loss cannot be less than 1d. per pound. Take the average weight of the bales as 300lbs. This shows the bale loss as 25s., and the total loss on 50,000 as £62,500.

This huge loss is not justifiable, because the farmers could by paying more attention to grading avoid it.

METHOD OF GRADING.

In the grading of produce it is necessary to work on definite grading principles, and wool is no exception. The general principle is always the same, that is, the separation of the inferior from the superior, and the work is based on the five chief manufacturing or commercial principles, viz., length and strength of the staple, and quality, condition, and color of the wool.

Length, strength, and quality in a general way decide the section of the trade in which the wool can be most economically used. Condition affects cost of scouring, and color has a direct bearing on dyeing. Although these principles must form the basis of wool grading, they must be employed in a commonsense and practical way. For example, in practice they simply divide the short from the long, the sound from the unsound, the fine from the coarse, the light from the heavy, and the bright from the discolored.

SHEARING.

The shearing on many farms is done under conditions that make correct grading impossible. It would not be practicable for farmers to set apart a building for shearing unless they owned enough sheep to warrant a shearing shed. Therefore the barn or some other building must be used.

It is absolutely necessary to prepare the building used for the shearing. First of all it must be thoroughly cleaned out, because straw and other vegetable matter is most objectionable in wool. Secondly, reasonable conveniences must be made for the handling of the sheep. A portion of the building should be partitioned off with hurdles to allow a few sheep to be kept in over night. Battens should be

used as a floor in the shed, otherwise a lot of wool will be badly stained. The battens can be made in sections and taken up and stored when shearing is finished. A boarded floor is also required to shear the sheep on. Convenient yards adjacent to the shed are also necessary for yarding and holding the sheep.

The portion set aside for the wool room should contain two bins for fleece wool and one each for bellies and pieces. Temporary bins can be easily and cheaply made with a few uprights and wirenetting. The most important point of all regarding the wool room is the wool table; this should be large enough to take a fleece easily, say, 10ft. long and 5ft. wide. It is on the wool table that most of the grading of a small clip is done. The best plan is to make a table top and rest it on trestles, as this allows of easy storing when shearing is completed. A box press completes the wool room furniture.

FLEECE TREATMENT.

This is the most important factor in the preparation of a small clip for market, because no sheep ever produces a fleece that is even in type, usefulness, and value, and the success of the grading largely depends on correct fleece treatment.

Not only are certain portions of the fleece inferior, but fleece wool correctly treated is always valued on a higher basis than skirtings, therefore any over-skirting, that is, the removal of any good wool, must result in loss to the owner. On the other hand if fleeces are not sufficiently skirted—that is, if short, dirty portions are left on—the whole fleece would be typed as skirty, and certain loss would result. It will therefore be seen that the work must be carefully and accurately done, and each fleece must be treated on its merits to obtain the best results.

The diagram on next page illustrates the portions that require removing on an average farmer's fleece.

Starting at the head a small portion—the top-knot—requires removal as it is short and fuzzy. The jaw pieces are matted and of low quality. The shoulder points are short and discolored. The frubby ends are really sweat dags from the armpit. It will be noticed that a fairly large piece is removed from the hind leg. This is because the wool on most fleeces runs away badly here, and is short and often hairy. On the britch end any dags and stains must be carefully removed.

We now come to the most important part of fleece treatment, which is the *back*. Most farmers in the wheatgrowing areas use their sheep on the fallows. Consequently the back portion of the fleece becomes heavily impregnated with earth and dirt. The earthy matter absorbs the yolk, making the wool dry, harsh, and tender, and unless the back portion is removed the earthy matter will penetrate right through the clean wool of the fleece, and when the wool is presented for valuation it will all appear as earthy back wool. Another important point is if the backs are left in they will reduce the yield to such an extent that overseas buyers cannot operate on account of the high freight charge. The buyers' calculations are based on the "clean" cost; therefore, unless at least 40 per cent. of clean wool is obtained the freight becomes a heavy charge. This means that unless the wool will give a 40 per cent. yield overseas competition is lost, and the wool will be bought by local scourers at a price well below world's parity.

GRADING THE FLEECES.

Most farmers' clips are small, the average being about eight bales of fleece wool. I will, therefore, deal with a clip of this size. Buyers prefer to secure their supplies in reasonably large lines. And, furthermore, any line of wool

below four bales constitutes a "star" lot, and cannot be offered in the main catalogue. On this account farmers should endeavor to make one main class of fleece wool as large as possible, and at the same time it must be reasonably even according to the classifiable principles—that is, 2½ in. or over in length, sound, medium to fine quality, reasonably light in condition, and a good color. With an average farmer's clip grown in the wheat areas this would mean that approximately 20 per cent. of the fleeces would need to be rejected. The remaining 80 per cent. or six bales should be even enough to be packed together. The 20 per cent. of rejects would consist of extra short, unsound, coarse, extra heavy, and discolored fleeces.

(In this diagram the best portions of the fleece are described as "average spinner's type," but if "burry," as often occurs in farmers' fleeces, this portion would be described as "average top-makers.")

What to do with the rejects is the next question. It will be seen from the above that they will be very mixed, and the only economical way in which they can be sold is to instruct the selling broker to pool them with the bag wools. In this way each different type will be bulked with other wools of the same type, and will eventually be sold at their true value.

PACKING THE ODDMENTS.

The oddments consist of "pieces," "bellies," "backs," "stains" and "locks." In a clip the size of the one under review there would be sufficient to make a bale of bellies over 250lbs. Any pizzle stains from belly wool of male sheep must be carefully removed. The backs would probably fill two bales. The pieces and locks may be packed in the same bale, providing a cap is placed between each sort. The stained pieces should be dried if wet and packed by themselves even if there is only sufficient to fill a bag.

LAMBS' WOOL.

In the preparation of lambs' fleeces for market they should be well shaken over the wool table to remove heavy fribby ends. And any very short fleeces shorn from very young lambs should be put in a bag by themselves, because length of staple is one of the most important factors in the sale of lamb's wool.

PRESSING AND BRANDING BALES.

Bales should be well and evenly filled, neatly sewn with twine—*not binder twine*—always remembering that the minimum weight for a bale of Merino wool is 250lbs. The branding should be neatly done with stencil plates on the cap and the front side, showing owner's brand on the top, description in the middle, and the number at the bottom. The letters and numerals should not be less than 3in. nor more than 4in. high. It is advisable to use the letter A in the description thus—AA for the main class and A for the rejects. When the clip is large enough to separate the ages and sexes—H for hoggets, E for ewes, and W for wethers. The earthy backs should be branded BACKS, bellies BELLIES, pieces PCS., locks LOX, and stained pieces STX. PCS.

STATE OF SOUTH AUSTRALIA.

RETURN OF EGGS AND EGG PULP EXPORTED FROM SOUTH AUSTRALIA TO EACH OF THE STATES AND TO OVERSEA COUNTRIES, FOR YEARS 1930-31 TO 1932-33.

W. L. JOHNSTON (Government Statist).

The Grand Total Exports for each of the years 1930-31 to 1932-33 were respectively £156,632, £232,907, and £306,712. The last year, 1932-33, shows an increase of £73,805 over the previous year 1931-32, and £150,080 over the year 1930-31.

The Grand Total Exports of Eggs in Shell and in Pulp in terms of Eggs in Shell is estimated to have been 3,000,000doz. for 1930-31, 5,200,000 for 1931-32, and 6,300,000 for 1932-33.

The following are the details :—

State.	Eggs in Shell.		Egg Pulp.		Total Value.

EXPERIMENTAL FEEDING TESTS CONDUCTED AT PARAFIELD
POULTRY STATION.

[By C. F. ANDERSON, Poultry Expert.]

A series of feeding tests are being conducted at Parafield Poultry Station with a view to ascertaining if suitable foods which are obtainable on the majority of our farms can be satisfactorily fed to poultry. The tests are each of 50 White Leghorn pullets, and commenced on April 1st, 1933.

The feeding is as follows:—

- No. 1 Test.—Morning—Wet mash composed of 1 part crushed barley, 2 parts wholemeal (by weight), $\frac{1}{2}$ lb. meat meal, 40 per cent. chaffed greenfeed.
Midday—1oz. wheat per bird. Night—1oz. wheat per bird.
- No. 2 Test.—Dry mash composed of same proportions as No. 1 Test.
Midday—Greenfeed. Evening—Wheat.
- No. 3 Test.—Morning—Wet mash composed of 1 part bran, 2 parts pollard (by weight), $\frac{1}{2}$ lb. meat meal, 40 per cent. chaffed greenfeed.
Midday—1oz. wheat per bird. Night—1oz. wheat per bird.
- No. 4 Test.—Morning—Wet mash composed of 1 part bran, 2 parts wholemeal (by weight), $\frac{1}{2}$ lb. meat meal, 40 per cent. chaffed greenfeed.
Midday—1oz. wheat per bird. Night—1oz. wheat per bird.
- No. 5 Test.—Morning—2ozs. wheat per bird. Evening—2ozs. wheat per bird. Greenfeed in season.

The following are the numbers of eggs laid by each pen from April 1st, 1933, to October 31st, 1933.

Definite conclusions, however, cannot be given at this juncture with regard to the various methods of feeding. It is necessary for the tests to complete the 12 months before any satisfactory opinions can be formed.

PAPERS READ AT CONFERENCES.

THE MILLING QUALITIES OF WHEAT.

[Contributed by MR. G. L. CHINNER (Loxton) at the Murray Lands East Branches, Taplan, October 17th, 1933.]

Various reports have appeared in the press of the efforts of the Minister of Agriculture, the Hon. A. P. Blesing, M.L.C., to discover the most suitable wheats for various districts in this State. It has been pointed out how essential it is to produce varieties of wheats that will return to the farmer a good yield and at the same time embody a strong quality so that Australian, and South Australian wheat in particular, may regain its former prestige, and thus command top price in the world's markets.

The liberty is taken of freely quoting Mr. Wenholtz, Director of Plant Breeding, New South Wales Agricultural Department, whose achievements entitle him to be quoted as an authority on wheat in general. Many farmers will recollect the time when most of the old Purple Straw varieties of white color and soft character were supplanted by some of Farrer's and Marshall's crossbreeds, *e.g.*, Federation, Yandilla King, Marshall's No. 1, Dart's Imperial, and Steinwedel. These, whilst being in general cultivation, offered no special claim to favor from the miller's point of view. Of all the new varieties, Federation proved a great disappointment, as its flour did not come up to expectations regarding quality.

Strong and Weak Flours.

The baking quality of wheat flour is ascertained by the number of loaves that can be produced from a given quantity of flour, such loaves to be of fine texture, good color, and pleasing to the taste. It is known that the most important factor in the determination of quality or strength is the gluten, in which the nitrogenous portion of the wheat is contained. However, it is not the quantity of gluten, but the *quality* which constitutes the determining factor in the baking quality. Flour that contains a large quantity of gluten of good quality possesses the capacity to absorb a large quantity of water, yields dough of toughness and elasticity, which will stand severe handling in the troughs and holds the gas generated during fermentation period. Baking with such flour produces a good loaf of bread.

Weak flours generally contain a low percentage of gluten of more or less poor quality, which reacts on the fermentation process, resulting in soft, sluggish doughs. The gluten may be regarded as comprising the walls of a cell, which are being subjected to pressure from within by the expansion of gas evolved by the yeast organism in the dough. A low quality gluten in the flour means that the cell walls, being thin and unable to withstand the pressure, burst. Such dough generally drives a baker to distraction, for the result is a very poor loaf.

Good quality gluten is generally obtained from hard wheat varieties—medium and poor quality from soft grain. It must not be assumed, however, that all hard wheats produce the best loaf of bread. The term "quality in wheat" means the quality of flour milled from such wheat. Therefore, grain quality depends on the gluten quality. This characteristic seems to be inherent in any wheat variety not modified to any extent by environment. On the other hand, the quantity of nitrogen, that is, gluten in a wheat variety, is influenced by hereditary environment.

Of the old wheats, such as Purple Straw and similar varieties—which in their day proved great bread producers—one has no hesitation in asserting that bakers produced a superior loaf of bread from those wheats than they are able to do from present-day grain. The commercial art of baking has been developing on lines very different from former times, being beset with difficulties that did not then arise. In many

[Papers Read at Conferences.]

cases the flour, first of all, lacks quality, the deficiency in which is being made up by electric chemical bleaching and the employment of various yeast foods or yeasts. The advent of machinery in the bakehouse contributes further towards the demand for stronger flours. The severe punishing the doughs are subjected to in power mixers—in combination with dividers and moulders—puts a severe strain on the fermentation process. Unless the gluten in the flour possesses sufficient quality to stand this punishing by machinery, this way of dough making defeats itself. By this fact the anomaly becomes evident of two flours of the same identity producing dissimilar results. The housewife and the small baker who do not use machinery, but hand-mix the dough and mould it, are able to watch the fermentation. Not being tied to time to take the dough whether ripe or not, the small baker may produce a pleasing loaf, whilst the machine-made loaf runs a bad second. The flour is blamed for this failure, whereas the blame should primarily be attached to the wheat. Occasionally some housewives, who are baking their own bread, often find their tempers tried by the sluggishness of fermentation and the resulting poor loaf, but in nine cases out of ten the cause of failure can be attributed to the wheat. Even bad milling may not spoil good wheat. The biggest miller in New South Wales once observed that good wheat milled on a pair of freestones and dressed through a ladder would produce good flour, but it is not possible to make good flour from poor quality wheat, even with the best machinery. No matter how the flour is treated, if the inherent quality of the gluten is faulty, then the result—bread—will be faulty also. In connection with this important question, the following incident of recent occurrence is related. A country miller friend asked me to see him regarding flour trouble, and reviewing the situation on the spot I soon came to the conclusion that the wheat—Baldmin—was responsible for the flour trouble. My friend could not believe this and had the flour analysed in the city, the test showing only a 5 per cent. gluten content from 67lbs. per bushel wheat. This seems hardly credible, nevertheless this fact alone accounted for the poor baking results. I am not exaggerating when I state that a loaf of bread from Baldmin wheat is a total failure.

Australian flour should contain approximately 10 per cent. gluten of fair quality, and this percentage has always been recognised in the world's markets.

For some years past all the energies of most agricultural colleges, as well as private breeders, have been spent in obtaining "bushels per acre." Quantity became the most important factor, and it has thus happened that there are more than 200 varieties of wheat grown in South Australia to-day. Gradually, but more insistently, as years went on, bakers began to complain about the loss of "kick in the flour. Millers generally were more or less puzzled, most of all country millers whose supplies were drawn mostly from round about the district in which the mill was situated. That many of these newer heavy-yielding varieties of wheat proved the cause of the trouble became evident.

Baking Quality and the Producer.

What has the question of baking quality in wheat to do with the primary producer? The farmers' foremost consideration must necessarily be to obtain the largest number of bushels. No one is desirous of altering this, but since Australia is an exporting country in wheat as well as flour, it remains of supreme importance that she meets competition by keeping up the "quality." Australian flour is now considered weak, and therefore not on a price level with strong flours, notably Canadian and United States spring crop. The English baker uses Australian flour primarily for its color, dryness, and sweet flavor.

The Chinese and Japanese distributors have both lately complained of the quality of Australian wheats and flours. The Eastern importers for years being used to the outstanding qualities of Canadian products severely criticise the New South Wales

[Papers Read at Conferences.]

wheat shipped and containing as much as 8 per cent. rubbish. They also complain of the flour, much to the surprise of the authorities. In China, where the native population is not using flour in the shape of bread, but makes dough balls and fries them in oil or fat, the flour that will return the largest quantity of dough from a bag of flour will command the best price in this market.

Some 40 odd years ago the late W. Farrer devoted his time to the improvement of Australian wheat, having in view the outstanding qualities of the red, hard Canadian varieties for the manufacture of strong flour. He succeeded in raising new varieties of the desired character—Comeback, Bobs, Jonathan, Florence, &c., Farrer, without doubt, succeeded in one respect better than he anticipated. He made a great wheat for the miller, but unfortunately a poor wheat from the farmers' point of view. His hard wheats "did not yield," and for this reason quickly disappeared, with the exception of Florence. Strangely enough, Florence, a cross between a Fife wheat and Nepaul skinless barley, survived, supplying the miller with a strong wheat which he required to mix with and build up the weak wheats he was compelled to take in the absence of any better.

All of the newer varieties can be termed only medium and poor flour wheats, the results of years of unchecked breeding by agricultural experimental stations and private breeders.

The private breeders' aims are to obtain wheat free from disease which will yield the most bushels. He had no means of comparing definite results until the progeny of his work became evident in the baked loaf of bread. The agricultural stations, however, possessed the means of ascertaining the probable quality much earlier, by submitting grain to a nitrogen test, and were in a position to reject anything not coming up to standard, but bushels always predominating.

Gluten Content of Wheat.

The following is the latest process discovered by a German chemist, Pelshenke, for ascertaining the gluten content of any wheat variety, even in its earliest stages of evolution:—

A small doughball of finely ground wholemeal mixed with 5 per cent. of its weight of compressed yeast is allowed to ferment in a beaker of water kept at an even temperature, and the time taken for the doughball to burst is regarded as a measure of the combined quantity and quality of the gluten. The quality of the gluten is determined by dividing this figure by the protein content of the wheat. It is stated that these tests of various wheats in different countries have given similar results to those returned from baking tests. It is also extremely useful in testing some high gluten flours where the difference in baking quality is not distinctively apparent in a straight baking test, but only becomes apparent in a blend test. It must not be assumed that the strongest flour, used alone, will produce the best loaf of bread.

Doctor Callaghan, of Roseworthy College, has adopted this process in his cross-breeding experiments. He will also be able to weed out such wheats as he finds unsuitable to meet the demand for quality. Since it takes 10 to 15 years to produce a new wheat variety, South Australia will have to draw on New South Wales, where Mr. Wenholz has succeeded in establishing varieties of outstanding character. In three years he expects to have 1,000,000 acres under crop in New South Wales.

South Australian millers are not asking farmers to depart from their bushel policy. To the contrary; until such time as they can be supplied with better wheats such as those now being bred in New South Wales the miller would appreciate a small supply of Florence. It is realised that Florence does not meet with special favor, but it represents that one variety in South Australian wheats that does supply the kind of flour millers and bakers are looking for. Doctor Callaghan is anxious to improve Florence by overcoming the bad habit of "shaking out." Millers are also considering the advisability of paying a small premium for good milling wheats, such as Florence and other similar varieties.

[Papers Read at Conferences.]

Again referring to the poor baking qualities of Baldmin grown in the middle north, it is not to be understood that this wheat represents the only variety of such character. By no means. Gallipoli, for instance, bears a very bad character amongst Victorian millers. Since baking tests have not been carried out by the South Australian Agricultural Department, and country millers do not possess the necessary instruments for doing so, there is much guesswork attached to the baking qualities of wheats which are drawn from small areas only. The larger town mills working in definite mixtures, where individual varieties of wheat have to be tabulated, do not disclose the results of baking tests made in their laboratories. Suffice it to state, according to results ex the New South Wales Agricultural Department, Gluyas, Federation, Currawa, Sultan, Caliph, Nabawa, and similar newer wheats are being tabulated as medium to poor, and therefore poor bread producers.

However, certain factors have to be considered that influence the baking quality, even in medium and poor wheats. Climatic conditions constitute one of these factors. Wheat grown in districts where moist and cool conditions prevail, is soft in texture and poor in gluten in comparison with similar varieties produced in hotter and drier regions. This explains the reason why mallee grown crops are superior quality flour producers compared with crops grown in districts with a higher rainfall. Since it is possible to-day to determine the baking quality of any wheat variety without having recourse to baking the flour, the millers are requesting the Agricultural Department to subject, first of all, the Show wheats to this test. The Department is sparing no effort to tabulate the individual characteristics of most of the exhibits, but as yet, the most important factor, both from the millers' and bakers' viewpoint is absent, namely, baking quality. Doctor Callaghan recognises this and is taking all possible steps to remedy the matter.

South Australian flour meets with severe competition overseas, and the local trade is burdened with high taxation costs. The industry is not spoonfed, but has to stand on its own feet. There is no export premium or bonus of any kind on export flour. Therefore, the State depends on farmers to foster this industry, and incidentally benefit themselves by growing good quality wheat.

A big improvement in the wheat industry will be noticed when the State produces good yielding wheats of high quality.

PINNAROO LINE BRANCHES, PARILLA, SEPTEMBER 26th, 1933.

FODDER CONSERVATION.

[By C. W. NEINDORF, Parilla.]

The writer of this paper makes no apology for bringing forward this hardy annual. We can rest assured that history will repeat itself, and that whilst this season now gives every indication of giving us a bountiful harvest of both grain and fodder crops, the year will assuredly come when there will be a shortage of farm-grown livestock and foodstuffs. So soon as good seasons come we are too prone to forget the lessons that we should have learned during times of scarcity.

One of the main essentials of livestock husbandry is the careful management of the animals, and not the least important of these is that, while the holding should be stocked to its fullest carrying capacity, care must be exercised to guard against overstocking. If the former point is to be observed, then during certain months of the year the farmer must be prepared to resort to hand feeding if maximum results are to be obtained from the flock.

Fodders can be conserved in the form of ensilage, grass, chaff, straw, and hay, but it is desired to draw particular attention to the conservation of oats and oaten hay. The oat crop is a valuable item in rotation of crops in the mallee. It increases the

[Papers Read at Conferences.]

fertility of the soil for the ensuing crop of wheat, and tends to reduce the ravages of takeall by starving out this disease. The cheapest method of handling oats is to drill in the seed on the wheat stubble with a disc before rain, if possible, either in February or March. Such early sowing is certainly something of a gamble, but if the crop does not make sufficient growth, on account of weeds, to give a cut of hay, it will pay handsomely as a feed paddock.

The better plan, however, is to work up a grass paddock in February or March, and seed it as early as possible—certainly not later than the middle of May. In the event of a wet season being experienced, an extra working would be advisable.

It is not necessary to have good fallow to produce a good hay crop, excepting possibly if the oats are sown on new land, where the fallowing would get rid of stumps, and so enable the binder to do a more satisfactory job. In all cases seed the crop at the rate of 1bush. of oats to 50lbs. to 70lbs. of super per acre.

Of the many varieties of oats grown in the mallee, I favor the following:—Algerian and Scotch Grey. From observations of the Fulghum oat, I consider it will ultimately replace Algerian. This oat ripens quite a fortnight earlier than the other varieties, and is an important factor in enabling the hay harvest to be got out of the way before the reaping of wheat is commenced. Guyra makes a prolific growth, and I am trying this variety for the first time this year. Palestine appears to be the best oat for grain.

A fair average for chaff grown on the farm is £2 10s. a ton, yet it is not uncommon for farmers to have to pay up to £10 for chaff.

All over the State men on the land are reverting to the use of the horse for farm power, and this is another reason why the ample provision of feed supplies should be made in seasons of plenty.

Too many farmers make the mistake of cutting the oat crop for hay when it is too far advanced towards the ripening stage. It can be cut with absolute safety much greener than is the general practice.

After having gone to the trouble of growing the crop, cutting, stooking, and carting it, some provision should be made to guard it against attacks by mice. To do this effectively, the writer suggests that the site of the stack should be enclosed with galvanised iron about 3ft. high. Take care, however, not to leave anything resting against the iron up which the mice can travel, and so enter the stack.

Finally, the stack should be covered with a thick layer of straw, and netting placed every 3ft. or 4ft. apart to keep it in place. For a stack that is held in reserve an extra layer of straw next year is advisable. If the stacking is done in dry weather, salt water can be sprinkled on every layer. If the weather is wet, crushed salt can be used.

POINTS ON KEEPING POULTRY FOR PROFIT.

[By S. R. G. CHENEY, Parilla.]

Leading authorities are all of the same mind, that, through years of testing, the best methods give best results. We need something better than "barn door" fowls to make the difference between profit and loss. For a growing industry that is six times the size of six years ago it goes to say that we have, and must still improve the strain. We need better breeding stock for the purpose.

The size and number of eggs are the main factors. To get these results, all eggs used for hatching must be 2ozs. or over (either for incubator use or for hen), fresh and clean, and of good shape—fresh, for sturdy chickens; clean, to help in checking vermin; and good shape, to be sure of no cripples.

The eggs should be laid by second-year hens, so that all young stock are given the best start possible—the older the hen the stronger the chick. The male bird used for mating should not be less than 10 months old. There are several ways of mating, but

[Papers Read at Conferences.]

the above methods are the ones used by nearly all leading breeders. Be sure the cockerel is from a good laying strain, good size, healthy and vigorous. He controls in progeny, size of egg, and body. One that has been dubbed or combed off is by far the best.

Care of chickens is a big factor in successful breeding. They must be kept on the move and kept growing, have plenty of green feed, grit, warmth at night, and fresh air.

When they are four months old all cockerels should be separated from pullets, locked up, fed, and fattened for market. Pollard soup is mostly used. The pullets are fed on mash, bran and pollard, and green feed in the mornings, wheat at night, thrown in a litter so that scratching and exercise are used in obtaining same.

I would recommend White Leghorns first, if closed up and fed on the intensive system; next, Black Orpingtons. These birds are splendid layers if the right sorts are obtained.

Gather the eggs twice a day, and give the birds plenty of clean, fresh water, kept in the shade. See that the birds are not sleeping in a draught.

Breed Black Orpingtons in August, and White Leghorns in September. They will then be laying when eggs are at the top price.

Fowl-houses should be inspected regularly. Keep down all vermin, using waste oil or kerosene. This is healthy for the birds, and a check on disease. Bluestone in water is a good tonic. Charcoal and shell grit are also needed. Brush all roosts with oil or kerosene every two weeks.

WHEAT OR MEAT?

[By R. C. JACOB, Geranium.]

It has generally been recognised and frequently emphasised that wheat was the ultimate objective of the farmer and that all other operations were more or less sidelines leading up to the production of the maximum crop of wheat at the end of the rotation; but since the disastrous drop in world wheat prices, largely due to the heavy surplus accumulated in America by the artificial manipulation of the market, has been slower in recovering, so that the wheatgrower puts his crop in with the almost certain knowledge that he will lose money on the project.

Undoubtedly, it is the development and maintenance of sidelines that has kept the majority of farmers in this district on their farms and off the dole. Unless something unforeseen occurs in one of the great wheat-producing countries to reduce that huge surplus, such as seasonal influences ruining existing crops or that big carry-over is destroyed by fire or some other means, there is little likelihood of a change in the position for the better, as we are still getting a premium through exchange. It is a question, therefore, of how long the State or the farmer on whom the State depends can carry on.

However, under the terms of the Ottawa Agreement, we have a golden opportunity of improving our position through meat—chiefly lamb, mutton, pork, and poultry. The position was made very clear by Colonel Copley at Congress. He stated that Britain was fulfilling her part of the Agreement, and the obligation was therefore on Australia to do her part. Up to June 30th last, 1,713,000 carcasses of mutton and lamb had been sent to England this year, leaving 2,586,500 still to be sent if available. The quota for 1933 is 4,300,000 carcasses, which would be the greatest number ever shipped, but it was unlikely that that number would be reached. After June 30th, 1934, there would be no quota as far as Australia was concerned. She could ship all she could produce. England consumed mutton and lamb as follows:—

	Tons.
Home grown	324,468
New Zealand	195,793
South America	94,112
Australia	57,802

[Papers Read at Conferences.]

and under the agreement there would be a progressive restriction upon foreign imports varying from 10 per cent. for the quarter ending March 31st, 1933, to 35 per cent. for the quarter ending June 30th, 1934.

The market is there, and if we do not seize the opportunity and make use of it we might not get such a chance again, but it will be of no avail if we do not study their requirements instead of expecting them to accept whatever we like to ship.

There is no question that the stock-carrying capacity of our districts as a whole can be increased on the larger farm, chiefly with sheep, and on the smaller with pigs and poultry, probably associated with dairy cows.

It appears to me that we would be wise to confine cropping wheat to the land most suited to it, and give it the best treatment possible, and sow the rest of our cultivated area to oats, peas, barley, or fodders for stock feed, and utilise all stubbles with grazing crops or even just top-dressing the pastures so as to increase the flock to the maximum and provide a reserve of hay, ensilage, or grain to tide over a lean time. It means departing from the system of farming that has been evolved and adopted from years of experience which under normal price conditions of wheat paid, but it offers greater possibilities of profit in the near future, and will certainly lead to increased yields, and so lower the cost of production in later years.

It is impossible to formulate any definite scheme. Each farmer will have to decide for himself what he can best do, as it is a matter largely of finance and local conditions.

It means definitely an increase in the quantity of super purchased, and in some cases possibly the purchase of sulphate of ammonia or other means of applying nitrogen. This is a difficulty we must overcome if we are to keep to our end of the Ottawa Agreement and get the most profit from our farms. Superphosphate is unquestionably the life-blood of our industry here.

Experiments and practice have proved conclusively over a period of years that 1 cwt. of 45 per cent. superphosphate per acre more than doubles the natural carrying capacity and increases the profit of our farms, but how many farms get it? At the Waite Research Institute this year even with a dry winter the increased bulk of fodder on barley on unfallowed land by the use of sulphate of ammonia and on pasture by the addition of Subterranean Clover is outstandingly self-evident.

It is well known and easily seen on many farms in this district how heavier or continuous application of super increases the growth of native clovers, so by increasing the super we increase available nitrogen by encouraging clovers, and it is certain that nitrogen plays a much bigger part in the success of all our crops than is generally realised.

It has definitely been proved that the amount of available phosphate and nitrogen in a soil greatly affects the drought-resistant qualities of the crops grown, also its rate of maturity; also that, by regulating the quantities of either, the composition of the pasture can be controlled within limits, and it is self-evident that the quality of the pasture is reflected in the quality of the stock grown on it, and the profits derived therefrom.

Having arranged for the feed, what are we to do about the stock to eat it? As wool is a much better figure, finance for stock should be simpler and not an unsurmountable difficulty; so, assuming finance is available, what should we aim at? All tests have shown that the cross-bred mother is the best for a fat lamb for the English market, using a Down-type sire, of which there is a fair selection. An even or any line of Crossbred ewe is difficult to get; the next best would be a Comeback, and if they are bred by Corriedale sires out of even-type Merino ewes they are more likely to be of even type than if bred by Merino rams from Crossbred ewes. Failing these, of course, the large framed, plain bodied Merino ewe is more easily secured, and will have to be in the majority for some years, but we must not forget that the English taste is against anything that savors or points to Merino, viz., the dark flesh and longish leg of mutton. They will pay more for the chunky, lighter colored flesh of the British breeds.

[Papers Read at Conferences.]

It is important to catch the early market, so lambs should be dropped about April, and every care taken that they get no check by feeding the ewes both before and after lambing if necessary, supplying a phosphate lick and having plenty of good water.

On smaller farms possibly cows and pigs offer as good if not better returns and, of course, one's natural inclinations count a lot in the successful management of either. A man must be fond of sheep to do any good with them, and love cows and pigs to put up with the continual drudgery they entail.

On the pig question we have had to change altogether our ideas of type, and there seems to be some uncertainty just what the type is, but certainly the over-fat, chunky, Berkshire type is done, and the longer, leaner, large Yorkshire pig, more suitable. This is a distinct advantage to us as large quantities of milk are not so essential, and they can be produced on open runs instead of stuffing them in sties. Pigs can be bred up quicker than most farm animals, so that it is easier to stock up with them. In the past the greatest trouble in the pig industry has been the lack of a definite export market, but this is our opportunity, and we should not lose it.

Another branch of the meat industry, beef, is important to Australia, but does not yet come within our scope. Although the English farmer does a lot in it, we cannot compete with the cheaper production of the cattle stations. Finally, eggs and poultry can be produced *cheaper on the farm than anywhere else*, and offers another avenue whereby we can utilise our grain and sell it as meat and return us a better profit.

BARLEY GROWING.

[By J. H. SPRATT, Lameroo.]

Preparation of Land.—We have found the best soil for malting or Cape barley is burnt wheaten stubble or grass land—stubble land for preference, as it generally gives a better sample. Worked over with a spring-tyne cultivator or skim ploughed, according to the conditions of land, in the autumn will allow any weed seeds or wheat to germinate. After the first rains have fallen work it once or twice with the cultivator or combine.

Seed and Pickling.—In selecting the best sample the first step to be taken, if possible, is to examine the crop from which seed is to be taken. It should be free from weed seeds and smut, also true to type, as the maltster does not like too much Cape barley in malting. Prior is the best malting variety. Formalin used at the rate of 1lb. to 40galls. of water is very effective in pickling. Divide the bag into two parts, shake, and immerse for two or three minutes; light grain can be skimmed off. Cape barley is more subject to smut than malting. Sow at the rate of 50lbs. to the acre with 80lbs. to 90lbs. of high-grade super.

Time of Sowing.—This will vary according to the break of the season, but experience has shown that May is the best month as May sowing gives the barley longer to mature. In 1930 we sowed one paddock during the latter end of April with malting barley, and reaped 34bush. to the acre of No. 1 sample. Really good crops can be grown with June seeding, providing the spring rains are good. The cool nights greatly assist barley during ripening, which is very helpful in a district situated a long distance from the coast.

Harvesting.—Barley should not be reaped before it is properly ripe or it will sweat in the bags. Great care should be exercised in harvesting malting barley, as good samples can be ruined for malting purposes by dressing the crop too close and skinning the grain. The ideal sample is that with about $\frac{1}{4}$ in. of tail left, but it is far better to leave it longer than that than to skin it. Adjustments should be made to the harvesting machine as the day warms up. The riddles should be set to avoid repeating as this is where a lot of damage results.

[Papers Read at Conferences.]

Marketing.—Submit a good average sample as soon as reaping has commenced to all the barley merchants. The price quoted on sample in the harvest period is usually the best. Malting barley should be put in new cornsacks as the buyers will not otherwise accept it for export.

Yield and Rainfall.—The following are the yields we have obtained over the past seven years:—

Variety.	Yield (Bush.).	Rainfall (1st May to end October). Inches.
1926—Malting.....	18	No. 1 sample off grass land 10-14
Cape	22	
1927—Sown for feed.		
1928—Malting.....	21	No. 1 grass land 7-57
1929—Malting.....	20	Stubble land and late fallow 6-28
1930—Malting.....	33	No. 1 grass land and stubble 9-96
Cape	35	
1931—Malting.....	20	No. 1 stubble 11-24
Cape	24	
1932—Malting.....	25	No. 1 stubble 10-26
Cape	34	

Effect on Soil.—It has been said that growing barley, especially Cape, ruins the soil and so impoverishes it that nothing else will grow. But I have carefully watched the land where barley has been sown, and there is no deterioration. Some of our best wheat crops have been grown where we have had barley.

Feed.—The paddocks where barley has been sown make excellent feed for all stock. Any heads that may be snapped off by the wind, or grain lost in harvesting, will be readily sought after by sheep which, with plenty of water, will soon put on condition. The grain that gets buried will germinate with the first rains, and makes rapid growth. It is ideal feed for ewes and fat lamb raising.

HYRE'S PENINSULA (LOWER), AT CUMMINS, OCTOBER 4th, 1933.

FENCING.

[By W. E. BRYANT, Cummins.]

Erecting new fences and replacing or repairing old lines of fencing are problems that have to be faced by all landholders every year. When erecting new lines of fences, once the line is pegged place the posts along the line before the holes are sunk, then one can sink the holes to suit the posts; the same rule also applies to renewing old lines of fences.

A very good method to follow is to put up each post as the work proceeds, with enough earth around it to keep it steady. Do this for one strain, then go back and ram them tight. If this is done it is possible to correct any fault if the posts are a little out of line in the bottom. In putting posts in line always use the line ahead in preference to the back line.

A class of fence used very extensively many years ago in the Terowie district was a wooden post every 40ft., a flat iron post every 40ft. placed half-way between each wooden post, and two corrugated droppers between each wooden post—strainers every 133½yds., 146½yds., or 160yds. as desired or angles in the line permitted, giving four 10ft. spans between each wooden post.

The wire spacing from the ground upwards was 6in., 6in., 6in., 6in., 8in., and 10in., a total height of 42in., the top wire being barbed. I have erected miles of this class of fence for 6d. per post, strainers included, without anything for droppers or iron posts. In replacing old lines of fence cut all wires and knots except the top wire, and split off broken posts. The old wires can then be removed fairly easily either by hand or with a horse and cart, taking out or taking off the top wire last.

[Papers Read at Conferences.]

In boring use a 9/16ths inch or $\frac{1}{2}$ in. bit; they clean better than $\frac{1}{2}$ in. bits, particularly if the posts are green or only partly dried. The holes for plain wire fences should be bored direct along the line, also even with the surface of the ground, because one or two holes bored out of line in either direction greatly increase the labor of pulling in the wires. Experience soon teaches the value of attention in this matter, particularly if working single-handed. If handling new wire I use a spinning jenny made from 3 in. x 2 in. hardwood—two pieces a little longer than the largest coil of wire, cut half through at the centre and crossed, leaving the surface level. Nail them together, and bore a hole through the centre; place on a block of wood 4 in. or 5 in. high with a hole through it, and drive an iron pin through both into the ground. Bore eight holes, two in each arm, so that they will be inside of each coil, and use four wooden pegs to keep the coil in position, and the wire is easily run in the line of fence.

For vermin-proof fences it is customary first to erect the line of fence, then plough out the trench, which requires very little straightening afterwards. In running out the netting use a horse and dray, the netting being placed on a bar on the side rail at the back of the dray, keeping the belly in the netting towards the fence. For straining, a stick with four $\frac{1}{2}$ in. hooks in it and a rope to pull around the post can be used.

In filling in the trench after the netting was tied on I always use a shovel, then the netting can be stretched where the ground is a little lower than usual. The earth is sometimes ploughed back into the trench, and while this is certainly much quicker and easier it does not make such a neat job when completed.

A point well worth remembering is to put the netting on the lower side of the fence, this greatly reduces the risk of floodwaters taking the fence with it. In using 36 in. or 42 in. netting with a barb wire above it two plain wires are enough if the netting is well buried, say, 3 in. to 4 in., because stock will not bother a netting fence like a plain wire fence.

In erecting cyclone fence I use all iron corkscrew posts, 5 ft. long, placed 15 ft. apart, with wooden sleepers for line-strainers every 7 $\frac{1}{2}$ chains, straining the barbed wire first and using lift shifting stays. Two of the cyclone special strainers were used—one a strain ahead of the other. By using two strainers the fence does not go slack. The cyclone fence was tied in three places to each post—top, bottom, and middle.

The cyclone Kinglock 26 in. fence is excellent for sheep, but for big stock it may not prove so serviceable. For subdivision the fence is placed 7 in. from the ground, with a barbed wire 10 in. above the cyclone—total height of fence, 3 ft. 7 in.

MOUSEPROOF HAYSTACKS.

[By F. J. JERICOHO, Cummins.]

The mouse-proofing of haystacks is a valuable safeguard against damage, and can be done without much trouble and expense. The stage can be made with ordinary wooden fence posts 6 ft. long cut in halves and put in the ground about 18 in.; the other 18 ins. will be quite high enough for the purpose—placing the posts about 6 ft. each way. Railway rails on the posts for rafters will give the best results, or round rafters of wood are quite satisfactory (5 in. diameter). Before putting the rafters on the posts place kerosene tins cut in halves on the posts. On the rafters ordinary mallee rails 8 ft. long and 1 ft. apart will serve the purpose.

For a stage 44 ft. x 15 ft. seven posts each 6 ft. long in each of three rows, six railway rails, and about 80 to 90 mallee rails 8 ft. long and 2 in. to 3 in. through will be required. There are no mice in my stack, which contains three seasons' hay, neither has there been any waste from the stage. No grass will grow within 3 ft. of the stage, and neither will any loose straw or hay which falls near the stage remain there, because the slightest breeze will shift it, which is a good fire protection.

[*Papers Read at Conferences.*]

THE ADVANTAGES OF FALLOWING WITH A FOOT PLOUGH AS COMPARED WITH OTHER METHODS.

[By E. A. PFEIFFER, Cummins.]

Fallowing is an indispensable item on practically every farm, and of recent years quite a number of different implements of various constructions and designs have been used. Although these have all given varying degrees of success, the undisputed fact remains that a good foot plough equipped with P-type shares is by far the best implement for the purpose.

The P-foot is preferred to the plate type of share on account of the tendency of the plate type to skip in the heavier classes of soils, especially if the ground worked still contains a fair percentage of stumps. Moreover, it has been proved in a number of instances that as even a depth of ploughing with plate shares cannot be obtained as with the P-type of share. One has only to compare ploughs fitted with these two types of shares and take note of the difference in set between the two to obtain some idea of this.

These, however, are not the only disadvantages of the foot plough fitted with plate shares. It must be realised that while the plate share usually has two bolts by which it is fixed the P-type is simply fastened by a pin which can be removed in less than half the time which it takes to remove the other. (Especially is this the case if the bolts have become rusted.

On the whole it can be said that the plate does not do such good work in practically any class of soil, for it is frequently seen that the swath cut by the plate share is not completely turned over. The plate share is an obsolete invention, for it was extensively used before the advent of the wrought steel or P-foot share because hand-forged steel shares were too expensive.

Fallowing has by no means been confined to foot ploughs nor ploughs in general, for quite a large area in recent years has been fallowed with the double-V cultivator, but without the desired success. While this method is much quicker than the plough farmers and agricultural scientists have realised that unless the ground worked is completely turned over fallowing is not a success. This is especially true if the ground is covered with a growth of weeds, for then the foot plough serves the double purpose of destroying weed growth and later on as the weeds decompose they revert into manure.

This in turn helps to fertilise the soil, and so makes the following crop more productive. Personal experience has proved this to be a fact, for the cultivator only stirs up the soil but does not turn it over, which is absolutely essential. It may also be argued that fallowing with a disc plough has definite advantages over the foot plough under certain circumstances, but such arguments are rather far-fetched, and do not carry much weight; for whereas some may hold that they could not have got a foot plough through certain classes of new land, &c., it would have been of definite advantage to them had they cleared their land sufficiently to allow the passage of a foot plough. Certain it is that had they done so they would not only have rooted up the land much better and made subsequent workings easier, but crop results would also have increased to quite an appreciable extent. This is a proved personal experience.

Furthermore, the use of the foot plough instead of the disc on new land is by far the more economical proposition; for whereas breakages on disc ploughs, especially on new land, are both frequent and expensive; breakages on foot ploughs, provided they are handled with a reasonable amount of care, are rare.

Opposition may also have it that certain soils—particularly those of a sandy nature—can be worked excellently with a disc plough, but it is also just as certain that these classes of soils are excellent for wearing out disc bearings, &c., and as the foot plough makes at least as good a job even in these soils the disc rather has a disadvantage than an advantage over the foot plough even in this respect.

[Papers Read at Conferences.]

When the purchase price of the various types of fallowing implements is taken into consideration it will be clearly seen that there is practically no difference and this, coupled with the advantages of the foot plough, leaves no reason why such an implement should not be purchased in preference to others.

METHODS I HAVE FOUND SUITABLE FOR GROWING GRAIN ON LOWER EYRE'S PENINSULA.

[By R. R. WILSON, Yeelanna.]

Wheat.—Referring principally to the Yeelanna district for wheatgrowing, I find that there are two methods of growing heavy crops. One is by adopting good fallowing methods, the other by cropping grassland. As my experience goes to show, grassland crops have proved by far the most profitable.

Fallowing.—The paddocks selected for fallow should be burnt clean if possible during February and March; breaking up with either the cultivator or plough should commence in July. The best results have been obtained with the draught cultivator, using a 6in. share. I harrow as soon as possible afterwards. The next working should soon follow with the cultivator across the previous working with an 8in. share. The following workings are just dependent on weather during September and October, or whether the farmer has sufficient sheep to keep weeds under control. The last working, however, before harvest is most important. I do not believe in closing the soil by means of harrowing or packing, but to leave it open to the sun during harvesting operations. During March and April if rain falls cultivate with light harrows attached to the cultipacker to consolidate the under layers of the soil and bring the seedbed as near as possible to the surface.

After the first winter or late autumn rain falls, harrow with points sharp and weighted down. I prefer sowing at the opening of June with combine and light harrows attached, and if it is anticipated weeds will make another appearance harrow again on the eighth or ninth day after sowing.

Grassland.—Burn old grass if at all possible. Plough well after first autumn rain falls and as quickly as possible, because the land dries out in a few days; immediately harrow and then cultipack. Harrow again after rain, and again cultipack if the soil is loose, and sow same as on fallow.

My reason for making the land so solid is because loose soil of over 2in. deep between the surface and the seedbed is disastrous to the wheat plant, and unless heavy rain falls after sowing on loose soil to consolidate it take-all will probably develop or the crop will not yield to expectations. The wheat plant must force its roots into firm soil to ensure healthy growth. A firm, even seedbed also encourages a better germination, which lays the foundation for a heavy crop. If the land is clean enough from scrub and shoots never use a disc implement. Disc implements are necessary on new country and save a lot of hard labor, but the sooner the land can be worked without them the better will be the results, because it is impossible to establish a level seedbed by a revolving disc. There are several golden rules in regard to growing wheat:—

1. Adopt a rotation of crops; a good one is wheat—peas (grazed with sheep instead of harvesting), then follow with wheat again, or fallow—wheat—oats—fallow—wheat—pasture.

2. Select good, clean, graded seed, and consider the quality. I prefer mostly the early varieties to enable seeding to be later.

3. Apply a liberal dressing of superphosphate.

4. Work the land well and at the correct time.

Barley.—The best quality barley will always be produced on wheat stubble land. After burning off the stubble give a light working to work in the ash, which also buries any weed seeds to germinate as soon as rain falls. Plough or cultivate as soon

[Papers Read at Conferences.]

as the rain falls, harrow again, and commence sowing at the latter end of June or early July. Pickle strong—1½ eggcups of formalin to a 4gal. bucket of water—this is sufficient to pickle three bags of barley; 1bush. per acre of good seed is sufficient, and 50lbs. or 60lbs. of superphosphate.

SHEEP HUSBANDRY.

[By M. T. GARDNER, Koppio.]

There is no doubt with many stockowners—and probably the fact has been strongly impressed upon sheepowners most particularly—that never before in their experience as flockowners have they been so hard pressed for sufficient feed for the adequate nourishment and profitable keeping of sheep during the winter months. Present indications prove although there is not cause for very great pessimism the question of paddock feed for the spring and summer has not yet been solved. With the recent abundant rains there is every hope that feed will grow, but there is the prospect, too, of stock having been kept so short of feed that it will be eaten up without any great reserve being left over for summer and autumn feed. It is in this respect that very careful management is required for profitable handling of sheep.

Last year, from early April until the end of the year, there was a superabundance of feed in the fields, and too much dried off, which I doubt has ever before been surpassed in poor quality.

In these years of contrast—the plenty and lean of paddock feed—it is a very hard matter to judge and maintain the correct stock-carrying capacity of our holdings, and we all know of instances where after the last year's excess of feed, landholders thought that more sheep could be carried this year, and in consequence losses have occurred.

The necessity for having a reserve of dry feed in the form of hay or oats has been brought home to many this year, and having had the experience of seeing sheep with insufficient feed, we should have learned the lesson to store dry feed against times of shortage of winter feed in the fields. A few tons extra of hay at the time of haymaking is not missed out of the crop, neither is the extra work to cut, cart, and stack same, but the value of it is appreciated in such a time as the winter we have just passed.

Good hay chaffed is the most economical way to feed sheep with self-feeders. A 10ft. feeder will accommodate 50 sheep, because not all of them feed at once, but a few can do so at a time, and there is plenty of time for sheep to feed if it is available for them. A 10ft. feeder is a handy length to shift about, and does not want such stout timber as longer feeders. Material for such should not cost more than £2 10s., and with care should last a long time, and even in years when there is dry feed in the paddocks the feeding of ewes prior to lambing is worthy of consideration. The feeders are very useful once made for feeding sheep if they have to be shut out of paddocks on account of stinkwort. Good water is also necessary.

To provide greenfeed for ewes and lambs oats drilled in with the combine very soon after the ground has become softened on burnt stubble is an excellent method, and after the sheep have had several months feed a good crop of oats can be reaped.

To get the oats in before the ground gets too hard after the first rains everything must be ready to get to work—oats cleaned and machine fixed up with good tubes.

After providing the feed for sheep there is a lot more to be done to ensure the best results from sheep, although it is not much use doing the rest if the sheep are undernourished. To save as much work and trouble as possible should be one's aim in life, not to dodge work, and if good fences with good gates are erected and maintained in good order, the trouble in looking after sheep is greatly reduced and rotational grazing can be carried out, which is the success of pasture management.

To have paddocks of rather smaller than larger dimensions is the best idea, and with heavy stocking for short periods the stock-carrying capacity increases.

A set of strong and sheep-proof yards is a great help and a necessity to successfully manage a flock of sheep, and a convenient woolshed is a boon when close to the yards. Failing this, sheep have to be taken away to be shorn, which is the next best thing.

[Papers Read at Conferences.]

I read recently of 2,000 wethers averaging 19lbs. of wool. This fact should set us all thinking. If so much country will grow so much wool there is no need to overstock, and the aim should be to have all the sheep well fed, and all working growing wool, and no "duds." If it costs no more to keep good sheep than poor ones, cull out the poor ones and keep only the best. It is said that medium strong wool with a lot of character is the most profitable type of wool to grow, but care must be taken to keep the character in it.

A lot of time and money are lost to the farmers each year through the blowfly pest. This can be overcome in most localities in South Australia by crutching. Do the lot—ewes, wethers, and lambs—twice a year is sufficient in most cases and, if not, do it three times and save the wool and save the sheep.

In many cases the raising of fat lambs for export is a very profitable sideline, and these can be bred from culled ewes from the wool flock, but care must be taken that all such lambs are sold or butchered. It is well to mark all culled for wool with a permanent earmark so that such sheep are easily recognised and not mated for wool production.

We have seen a lot of adverse press reports lately about classing of farmers' wool, and I do not intend to say much about this subject more than it is up to all who grow wool to try to grow it as true to type as possible, and then try and sort it out and put it together in bales in its correct classes.

Buyers are not so much concerned about the type of wool they buy as much as whether it is mixed types. We are told that every type of wool has a "type" value, and that each type is valued separately. Therefore, we see that with mixed types packed together we get mixed values, and the buyers in such cases to protect themselves give under-values. Let us try to market this valuable product to make the most money for ourselves and for our State.

THE CARE OF MACHINERY.

[By C. A. NEWBON and W. P. BARTLEY, Wudinna.]

Farmers generally are seeking a way to reduce the cost of production in connection with wheatgrowing. This Branch of the Bureau has asked members of the Advisory Board of Agriculture to give us advice as to how we can reduce the cost of production. The answer is always the same, "Grow more wheat to the acre."

I maintain that every farmer throughout the whole world is trying to grow more wheat per acre, and the more wheat they grow the more they will reduce the price of this product. My paper is entitled "The Care of Machinery," and I will endeavor to show in a small way how by the care of machinery you can reduce the cost of production "just a little." First of all a farmer should overhaul his machinery before starting out on a new season's work.

The stripper and harvester are machines that will last for many years if they are well looked after. A farmer will send his motor car to a garage to be overhauled, but his harvester, which is more important, he will overhaul himself. But there are times when he does not overhaul it until something breaks. Then very often a farmer is held up at harvest time with a broken bearing; he is sure to lose one day's reaping or perhaps a full week waiting for parts to come by mail or train.

A harvester's main bearing is that bearing which is placed between the pinion and the flywheel; this bearing is mostly a roller bearing. Before starting harvest it should receive attention. If the rollers are worn and there is sufficient room to allow another roller to be placed in the bearing one roller should be put in. If too much space is allowed between the rollers the chances are that one roller will jump out of place, become jammed with other rollers, and break the bearing. The bearing will break a casting, and if the machine is not stopped in time more damage may be done.

[Papers Read at Conferences.]

The cost of one small roller will be nothing compared with the cost of a bearing and a casting and the loss of time in good reaping weather. All other bearings should be watched for signs of wear, and all chains and belts tightened a little to take up slack.

The wear on the main axle and the main wheel are very often the cause of the crown and the pinion becoming very much worn. With regard to the main axle and the main ground wheel of the harvester and the stripper they are very much the same, and should be dealt with in the same way. The machine should be jacked up, the wheels taken off, and the main axle taken out. The worn parts of the main axle should be built up to fit the wheels. This work should be done at a motor garage where there is a man with a torch. I understand that they are best built up with bronze. The cost of a main axle is about £5, the price for building up is about £1 per end. I have seen the crown and pinion of a stripper chewed up through cutting into one another. The price of a new crown is over £2, but it would be useless to buy a new crown unless you have the axle and wheels trued up.

Another advantage of the oxy-welding plant is the important work of repairing castings. No casting is too large or too small to be repaired with the oxy-welding plant. The price of doing these jobs is usually based on the price of the new casting. A few shillings may be saved on the price of a new casting, the sales tax, and the freight. The freight in some cases is a third of the cost and sometimes more.

Some farmers are in favor of doing their own repairs; that may be all right if the farmer has some knowledge of blacksmithing, but when it comes to building up the main axle of a harvester or a stripper it is a job for a tradesman and not for a farmer. With the oxywelding plant there are repairs that can be done better and cheaper than with the blacksmith's forge, and it is useless for a farmer to tackle a job that is too big for him. He must remember that his own time is worth something to him, and also that the tradesman has to live, and it is not quite fair to give him only the jobs that the farmer cannot do himself. Every little bit that you can do in this way is a little bit off the cost of production.

Harvesting and Care of Machinery.—The first consideration should be given to the machines to see that they are in order to avoid delay when crops are ready to harvest. Farm machinery being expensive, the farmer should take every care of it. Before starting work in the paddocks each machine should be overhauled, and worn or broken parts should be repaired. Spindles, for instance, can be filled with bronze and re-laid at a much less cost than buying new ones, and will wear just as well. I favor the stripper and power winnower for harvesting; by this method the crop can be harvested in much less time, with less risks of delays by breakages. At the same time you are in a position to save all cocky chaff, which is of great value in drought years.

If the crop is down badly it can be taken off with a stripper with good results with perhaps a little more labor, but probably less expense per bag. Personally, I think that we have more crops on which it would not pay to use the header or harvester at the present price of wheat and oats, than otherwise. The heaps should be made longways and not too wide; by making the heaps this way the floors do not cut up as badly as round heaps, and there is less risk of being damaged by wet. Narrow heaps are much better for the power winnower. To get the best results while cleaning the grain it is necessary to leave the machine standing as level as possible, and the sieves should be in good order. The sieves should not be too close, and the top one should have plenty of slope; I should say from 4in. to 5in. on a power winnower. The tailboard should be as low as possible for cleaning wheat. For cleaning oats only one sieve should be used—a large-lipped sieve. A piece of tin about 8in. wide should be nailed underneath the front of the sieve in order to reduce the wind as the oats fall to the sieve; if the full amount of wind is blowing right through the sieve, a lot of grain will go over the tail of the machine. For oats the tailboard should be fairly high on a power winnower; this is the reverse to cleaning wheat. For cleaning wheat the machine should travel faster than for cleaning oats. After harvesting is completed all machinery should be placed in a shed.

[Papers Read at Conferences.]

**NON-IRRIGATED FRUIT-GROWING DISTRICTS, NURIOOTPA,
NOVEMBER 7th.**

FRUIT DRYING.

[By A. J. CHAPMAN, Light's Pass.]

It is not my intention in this paper to deal with fruit drying in detail, but rather to offer some observations regarding the quality of non-irrigated dried fruits, and to suggest how the standard of quality can be improved.

The quality of the fruit produced has a seasonal variation over which growers have no control, but a considerable improvement can be affected by the exercise of more attention to detail in drying practices.

Too few growers visualise their fruit further than the packing shed door. If we were to critically examine our product from the consumer's aspect and ask "Is this fruit as clean, true to type, and as appetising in appearance as we can make it?" I feel sure that much of the faulty fruit would not be offered for sale to become a drug on the market and adversely affect the industry.

The outlet for the bulk of our surplus dried fruit is Great Britain, and whilst on that market we enjoy the advantages of preferential duties and exchange premiums. To effect sales, the quality must compare favorably with the world's best. Modern grading machinery and packing shed practices can do much towards turning out an attractive and saleable product, but the real responsibility of quality rests with the producer.

CURRENTS.

There is roughly about 2,000 tons of this fruit produced in the non-irrigated areas of South Australia, representing about one-eighth of the Commonwealth production, so that any improvement in drying practice which will tend to raise the grade will have an appreciable effect on the Australian pack.

The chief criticisms levelled at our currants are excessive moisture content and lack of bloom and body. Although there has been a marked improvement in regard to the former, much of the fruit delivered still contains too much moisture for safe transport through the tropics. London buyers detest currants which are at all sticky; they demand a fruit answering the description of "dry and free-running."

In regard to lack of bloom and body, this fault can be minimised if the fruit is ripe at the time of picking with a Beaume of at least 13.5°. Shade drying, whether on racks or trays, will always produce fruit of better bloom and body than sun drying. Shortage of trays or rack space is false economy.

The one practice which is outstandingly responsible for the lowering of the grade is that of "rubbing off" before the currents are quite dry; the breaking up of the bunches and "buck" riddling whilst the fruit is still soft causes some berries to burst. The sound fruit becomes sticky, and small particles of dirt and stems adhere to it, giving the fruit a grubby appearance, which is even more apparent after grading. This precludes otherwise top-grade fruit being classed as such.

"Sweating" is another essential practice for which wooden containers either of the sweat box type or petrol cases can be used. The practice of sweating currants in large heaps is not conducive to high quality. There being no ventilation under this method, excess moisture and heat cannot readily escape, the result being fruit inclined to stickiness.

TREE FRUITS.

With the exception of prunes and plums, tree fruits are dried in halves or sliced, and for this reason added care and attention on the drying ground are necessary if dried fruit of a high quality is to be produced.

[Papers Read at Conferences.]

The presence of dust and grit on the cut surfaces is a common fault, and whilst a sudden dust storm is sometimes responsible, it is more frequently caused through the drying trays being spread on the ground. In this way, they collect dirt on the under surface, and on being stacked the loose dirt is shaken on to the fruit on the tray beneath.

The provision of wire racks on which to rest the trays is the best method of overcoming this difficulty; failing these, lengths of round scrub timber 4 in. to 6 in. in diameter placed on the ground will answer the purpose quite well.

In taking the fruit off the trays a certain amount of handling is unavoidable, and it is at this opportune time that blemished and otherwise faulty fruit—which does not conform to the general sample—can be eliminated most economically. A point worth remembering is to avoid unnecessary handling, but when it is necessary to do so, do something to improve the sample.

APRICOTS.

To produce dried apricots of good color and texture such as is required for export, apricots should be picked ripe, but sufficiently firm to retain their shape on being dried. Cutting should take place at the earliest possible moment after picking, preferably within 12 hours.

Sulphuring is one of the most important operations. The cut surface should not be allowed to become dry before being placed in the sulphur chamber. The provision of several small chambers of boxes is better than one large one. The somewhat common practice of cutting all day and sulphuring all night is wrong.

The time of sulphuring depends on the condition of the fruit and weather, about six hours is usually sufficient. A quick burn of sulphur with adequate ventilation in the chamber will fix the color quickly without unduly impregnating the fruit with sulphur. It may be of interest to note that the time occupied in drying has a very decided bearing on the sulphur content of the dried article. Following the showery and cool weather experienced last year, fruit analysed in London only showed 700 parts of sulphur dioxide per million as against the 2,000 parts allowed, so that under bad drying conditions longer sulphuring is indicated.

Apricots should not be removed from the trays whilst warm or until sufficiently dry, the wrinkled appearance of fruit which has been handled in this state is not at all attractive when packed.

PEACHES.

Much the same treatment is required for peaches as for apricots, except that a longer time must usually elapse between picking and cutting. The color of the peaches produced in these areas does not as a rule compare favorably with the river production. In the case of the Elberta—which is the principal drying variety—the trouble is usually the result of the fruit being picked before it is sufficiently ripe, thus necessitating a longer period in cases prior to cutting. The fruit is then inclined to wilt, and does not ripen to a bright color. Dry growing conditions are also responsible for dark-colored fruit.

PEARS.

Of the dried fruits produced pears provide the greatest variation in color and quality, and with a few exceptions this fruit is not a credit to the industry. The class of fruit we should aim at producing is that of a light straw color, free from pink or brown edges. This type can only be produced by careful treatment from the time of picking until the drying is complete.

The fruit should be mature before being picked, and should be stored for preference in a cellar or other cool place. The judicious use of damp bags in hot weather to retard evaporation will help. The fruit, in fact, should receive the same care as though it were intended for canning.

Cutting should take place when the pear is just past the canning stage or, in other words, lemon yellow; if allowed to become over-ripe the color of the dried article will suffer.

[Papers Read at Conferences.]

The fruit should be placed in the sulphur chamber as soon as possible after cutting and before any discoloration takes place—the time of sulphuring may be anything from 12 to 18 hours, until the fruit is soft to the touch right through.

In drying, the trays should be spread in the sun (if not too hot) for two or three days, then stacked and shade dried. An occasional day in the sun after being stacked for several days will hasten the drying without impairing the color.

PRUNES.

The quality of this fruit is generally good. South Australian prunes were this year exported to New Zealand, Canada, and London. In each market they were well received, and prices realised indicate that the quality compared very favorably with Californian and South African fruit.

There is a tendency on the part of some growers to over-dip and under-dry. The variation in the skin texture of the different varieties of prunes makes it almost impossible to lay down any hard and fast formula for the strength of dips. It is only by trying a small quantity of fruit to be dipped each day that the quantity of caustic soda can be gauged.

It is not necessary to crack the fruit to the extent often practised, the removal of the bloom is all that is required, and although the drying period is prolonged the fruit will be heavier and of better quality.

ORGANISED MARKETING.

[By D. FARMER, Angaston.]

Much to-day is heard of the term "orderly marketing." The expression first came into use during the years when the American Farm Bureau Federation was being organised, 1919-1921. The term is not a simple mathematical formula for solving primary producers' marketing problems, but implies in a general way price stabilisation through control of the flow of the product to market. In the liberal sense it may be defined as the marketing of the commodity at the right time and place, in the right quality and quantity. At the same time price is the final great regulator. The law of supply and demand never abdicates its throne. When saturation point is reached in consumer demand a lower price will register that fact. The difficulties that confront every primary producer are admittedly great, but no grower can blind himself to the fact that only by collective, consistent, and effective organisation can he obtain the best results for his labor. Better methods of production, better grading of goods, more direct and economical marketing, better machinery of finance and credit, better publicity, oversight of distributive charges, study of competitors' methods, study of markets, we can all assist towards a solution, and this can only be effectively accomplished by organisation of producers.

Organisation is apparent in every phase of life to-day. It has been well said that the obvious handicaps under which the primary producer labors is that whilst other branches of industry have reached by organisation relatively high stages of organisation, and are therefore able to gain advantage over the farmer, he suffers by reason of no fully organised effort. Now, why is the farmer or grower so prone to reject organised methods of marketing? Because in farmers and growers there is a definite spirit of individualism. The tendency of farming is to foster a spirit of self-reliance. The man who controls the use of a tract of land, who decides the nature and kind of all the processes of cultivation, must depend on his own judgment. He may, and oftentimes does, consult with his fellow growers, but instinctively he acquires a habit of independent action and of general self-sufficiency. In short, the bias of the growers' mind is individualistic. For these reasons the idea of combining with others in business transactions, and in some degree surrendering his independence is not congenial, and co-operation or organised effort with others can only be advocated as a business proposition on the ground that it will secure by collective effort definite trading economic advantages.

[Papers Read at Conferences.]

Farm or orchard management has two distinct branches (1) technical, (2) economics; in other words, practical farming and business organisation. Agriculture is primarily a business. It has sometimes been described as an art, and sometimes as a science, but though its pursuit involves technical skill it does not differ in that respect from any other industry. Whether the grower wins from the soil only the means of sustenance for himself and his family, or an excess of products for exchange or sale, his object is to make an income in kind or cash, which is the object of all who engage in business. With so many units in production, with such diversity of character and thought, the trouble arises in making growers appreciate the fact that they are virtually shareholders in a business with others, and that unless they combine or organise they become definite competitors. Especially is this so in the case of the small grower whose stake in the particular commodity is small.

Free competition leads inevitably to instability, because stability is impossible without planning, and planning is impossible with such a large number of unknown factors as free competition involves. To plan a marketing programme demands rare skill, but where competition is free it is impossible, for your plans are dependent upon a knowledge of the supply and demand of markets, both of which are beyond the control of the grower.

The victim of this chaotic condition is the grower, and it is in his interest to-day that freedom of competition should be so far curtailed as to make possible a sound marketing programme. What the grower needs to-day is not more competition in his particular commodity, but more co-operation or co-ordinated effort in order to stabilise marketing and keep him in employment.

MARKETING BOARDS.

Any intelligent grower will admit that the thing most desirable is stability in marketing; some assurance that the sale of that which he produces will at least secure to him costs of production. It has been indicated that free competition leads inevitably to instability, and that this freedom of competition should be curtailed or controlled to make possible a sound marketing programme. Such control means restriction of trade, either by the producer or by the State. Control by the State carried to its logical conclusion is communism, but control vested in the hands of the producer can co-ordinate marketing activities, and permit of a sane policy of distribution. It is significant that all over the world steps are now being taken to appoint Marketing Boards for various products. Vast changes have been witnessed in the past 10 years or so in the science of agricultural marketing. Agricultural economics are receiving to-day more attention than ever, and much as one may deplore the passing of individualism, even the most conservative types of producers are recognising the new order of things, and are prepared to accept new ideas on marketing. Within the past month or so by an overwhelming majority the farmers of England have declared themselves in favor of the Government Milk Marketing Scheme, under which the sale and collection of milk is controlled by a Board. This Milk Marketing Board will control the national milk supply and its sale. The scheme involves an annual value of between £50,000,000 to £60,000,000 and the livelihood of more than 250,000 producers. In Spain citrus exporters must be registered in the official register kept for the purpose at the Commercial Section of the Ministry of National Economy. In October, 1930, the Bulgarian Government set up a special Board for the purchase of bread-stuffs, &c. The administration of this Board included accounting, control and inspection, and in a very short period of its activity the Board succeeded in not only checking the continual fall in the prices of exported cereals, but was even able to raise the price above world's parity. In Greece there is a Greek Currant Control Office; the trade in Argentine fruit has of recent years been re-organised by dealers and growers; whilst a Bill was introduced into the Imperial Parliament called the "Agricultural Marketing Bill, 1930," which has as its main purpose the enabling of schemes to be made for regulating the marketing of agricultural products by producers. Other illustrations could be cited, but these indicate the trend of thought towards organised

[Papers Read at Conferences.]

marketing methods in other countries, and the advisability therefore of Australian producers recognising such, so that they may be able, by organisation, to face organised competition by other primary producing exporting countries.

When the Bruce-Page Government came into power one of its major planks of policy was organised marketing. Various Boards were created, legislative control was introduced, and this was followed by a great outcry against Government interference in business. It is significant that to-day, after a lapse of about 10 years since such measures were first introduced, producers of wheat, butter, oranges, milk, and other products are seeking a way out of their difficulties by advocating some system of legislation for their respective industries. Now, why the necessity to bring the Government into it at all? For the reason that voluntary organisation amongst producers has not proved sufficiently effective to ensure the full efficiency desirable in national marketing schemes, owing to the fact that the measure of stability which such voluntary organisations have achieved has been seriously affected by the action of growers in not supporting measures primarily designed for their benefit, or of selfishly taking advantage of voluntary organised schemes for their own particular benefit.

Where, however, an industry has been given certain legislative powers to assist it to control its own affairs, any subsequent organised marketing scheme launched must recognise certain basic economic laws. There are three interested parties in primary production: (1) the original producer; (2) the middle man; and (3) the consumer. Of these three the consumer is the most important. The grower is apt to assume that not only is there a constant demand for his foodstuffs, but also a necessitous demand. Both these assumptions are false. The consumer turns to various substitutes and the demand for food is very elastic. In addition, there is a definite saturation point in consumer-demand, and when that stage is reached a lower price will register the fact. One of the most difficult problems in agricultural marketing is that of a correct sale and price policy. In marketing farm produce, the elements of bargaining and price-strategy enter, and the ideal should be to keep the consumer consuming, and the producer producing, avoiding shortage and undue carry-over. Further, the producer cannot ensure success by copying merchandising methods of successful manufacturing concerns—his problems of marketing are totally different. The manufacturer can control quantity—the producer cannot; he can control quality—the producer is subject to climatic conditions; he has a greater field of expansion—the producer's field is definitely defined.

A good deal is heard to-day regarding the evils of price-fixing by producers. Intensive grower-organisation is a pre-requisite to successful price-control, but there is no reason why the domestic or home consumption price should not be pushed to that point at which the return to the grower will bring his position into favorable comparison with that of others. Growers' interests are better served by stable prices than by violent fluctuations, and if it is possible to obtain to some measure of economic equality with other branches of industry in the domestic market, that need not preclude later adjustments to meet changing conditions. The accusation is also made that where control is brought into primary production, it is contrary to true economics. If by this is meant control as applied to the law of production, then I am inclined to agree, but if it is meant control as applied to the law of trade, then that is a different proposition. All trade laws are man-made, and if the proposal to control is economically unsound, then so are many laws of trade which permit holding by an industry of supply and releasing to demand at will.

Production calls for individual effort, but from that stage onward organised effort must commence to obtain best collective results. Once out of the grower's hands his product passes into the hands of others who will all charge him for their services. The road from farm to consumer may be long, crooked, and full of toll-gates, but

[Papers Read at Conferences.]

organised effort can ensure that no tolls are taken except for actual service rendered. The use of co-operative association by growers has increased considerably in recent years, but that in itself should not affect intensive organisation amongst growers themselves.

Control legislation, orderly marketing, organised marketing, may all be somewhat of a new science, but it behoves every grower to keep his mind open and receptive to the new ideas, and to adapt himself to the torrent of change that is taking place in primary production methods the world over. The old-fashioned, casual ways of marketing have now become dangerous. There is a new knowledge abroad in the world. Gradually, growers are learning to have a greater measure of control in their affairs than their fathers ever dreamed of. Admittedly organised marketing means the passing of individualism, and its innovation has met bitter opposition, both from growers and interested parties, but it has come to stay. No amount of study of the past fits us to pass judgment upon what may or may not be done in the future. Changing conditions are sure to justify and necessitate further changes in the marketing of primary produce, and agricultural statesmen might well confer and formulate and announce production policies having regard not only to interstate and national programmes, but also with regard to international competition.

PICKING AND HANDLING FRESH FRUIT.

[By L. PLUSH, Light's Pass.]

In pre-war days Australia consumed most of her fruit production with the exception of apples, but since that time the output has increased to such an extent that we are exporting at least 50 per cent. of our fruit, either fresh, as with pears and apples, or canned, in the case of pears, peaches and apricots. Competition with other countries is becoming keener, and we are finding it increasingly difficult to make sales overseas at profitable prices.

It behoves us to take more care in handling, packing and grading, and to make the fruit attractive. In quality our product is equal to that of any country, but how often have careless grading, handling and packing spoilt our good name and good fruit?

The paper is divided into two main subjects:—The care and handling of fruit for canning, and the picking, grading, and packing of fresh fruit for export.

In dealing with fruit for canning, there are four main points to watch—Size, cleanness of the crop from disease, correct stage of maturity, care and grading after picking.

GOOD EVEN SAMPLE NEEDED.

It is essential to have a good even sample for canning, and, of course, not too small. In years such as this I advise every grower of apricots and peaches to thin his crop where necessary to allow the fruit to come to normal size. Small fruit is costly to harvest, of little or no use for canning, and distressing to the tree for next season.

Fruit clean from scab or other blemishes, such as limb rub, leaf mark, and codlin infestation, is essential. Misshapen fruit must be rejected, and put aside for drying or sold for jam.

Picking apricots for canning is a difficult job, especially when a garden is situated any distance from a factory, and it is almost impossible to pick the fruit without having to grade it for ripeness. It is a good plan to grade every bucket as it is emptied into the case, the riper or blemished fruit being put aside and used for drying or sold separately for jam.

Apricots should be picked when very firm and poured gently in cases, which should be slightly bumped and well-filled before dispatch to the cannery. As soon as the fruit is picked it should be put in the shade and kept cool. Never put it in a hot shed over night. It is much better in the garden.

There are three varieties of apricots good for canning—Moorpark, Tilton, and Trevatt. Of these three I prefer Trevatt.

[Papers Read at Conferences.]

PEACHES AND PEARS.

Peaches need much care, but are not the same problem as apricots. The fruit is firmer, and generally the weather is cooler at picking time. Clingstones are now chiefly used for canning, although some freestones are still canned for local markets. However, in a few years no freestones will be canned. The fruit may be allowed to become well-matured before picking and several pickings should be made. Grading, out all blemished fruit helps, and sizing adds to the appearance. The same care in placing the fruit in cases, as with apricots is necessary. The finest canning varieties are Golden Queen, Phillips, Pelora, Levis, and Goodman's Choice.

Pears are a slightly different proposition from apricots and peaches. The fruit should not be picked too early, but allowed to ripen sufficiently, before picking begins. This should be all done with a ring 2½ inches in diameter, the fruit graded for codlin moth and mis-shape, and packed, not placed indiscriminately in the case, which should be lightly bumped, with the lid lightly and evenly pressing on the fruit. It is an advantage to put a crumpled piece of newspaper on top of the fruit before placing the lid on, to prevent bruising.

HANDLING.

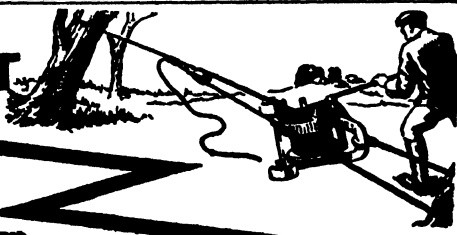

Much depends on the way all fruit is handled after picking as to whether it will arrive at its destination in good order. Empty cases should be kept in the shade prior to filling, and care must be taken not to allow sand or dirt to get into cases. A good plan is to have a number of battens on which to stand full cases, because sand will enter, when filled, even with the greatest care. On very hot days place wet bags on the full cases. Considerable damage can be done by rough handling of cases of fruit.

A large buyer of canning and jam fruits told me that he did not mind paying higher prices for fruit which arrived in good order, because there was little or no waste, which was the greatest trouble he had to contend with. One man may take care to grade his fruit, and handle it carefully, and 100 dozen tins, perhaps, are canned from a ton, whereas another grower's fruit will give only 80 dozen tins.

APPLES AND PEARS FOR EXPORT.

The second subject for consideration is picking, grading, and packing apples and pears for export, or local markets.

TEARING THEM OUT

Is the regular job of the Monkey Grubber; in fact it was born to the work.

TREES AND STUMPS, it matters not, they are torn out with roots intact in a single job quickly done. Run to the job like a bare trunk, and worked in the same manner as a stump to reveal. It develops the power of the man progressively applied, and always under perfect control.

In any position, so long as the operator has space for a footing, the machine is efficiently worked. An Automatic Gear allows a hand to be heaved or released at will. Besides the great power and portability there are embodied other labour saving features, such as special rope coupling, rear shifter, engine block, etc.

Applications in Australia, New Zealand, Great Britain, South Africa, the Americas, as well as Persia, India, China, Central Africa, F.M.A. the East and West Indies, record the merits and applied its help.

THE "MONKEY" GRUBBER

Is fashioned from material mined and made within the Empire, by Empire craftsmen, to assist with the fast and efficient development of Her Majesty's resources.

[Papers Read at Conferences.]

Before starting to pick these fruits, make sure of their maturity. The best methods to arrive at a correct decision for apples are by the iodine test, color test, and by cutting open a number of apples and examining the seeds, which should be dark brown. The last test is the most reliable, although the color test is good. Color charts are available from the Department of Agriculture. The iodine test is very unreliable at times. When satisfied that the fruit is ripe enough, see that the pickers have short finger nails, and set them to pick with a 2½ in. ring, not smaller, for the first picking.

Pick the fruit and cart to the shed, postponing grading for at least a day. Should the fruit be graded at once, do not have it packed for at least a day, and two days are better. Bitter pit does not always show at once, nor do bruises. This is not always convenient, but it is better than having several hundred cases rejected at Port Adelaide. Apples and pears should be handled as carefully as eggs, because if slight bruises do not show at once, they do later, when unpacked. Grading is the most important part, and generally is not done thoroughly enough. It is the half-dozen apples in the case which should have been rejected which may make a difference of 1s. to 2s. a case when sold overseas. Those six apples are expensive to the grower. The buyer has to protect himself and to allow for a percentage of bad fruit in each case.

CARELESS SIZING.

One of the biggest mistakes packers make is careless sizing, and a good pack is almost impossible without good sizing. The four sizes used for apples are 2½ in., 2½ in., 2½ in., and 3 in., and they are mostly exported with the size stamped on the case. The retailer in England sells his fruit by units and dozens, not by weight, and he likes to know how many apples are in the case he is buying. For instance, he buys a case of 2½ in. apples; that case may have 150, 165, or 175 apples in it, and still they are 2½ in. apples. Therefore, the sooner the count system is adopted for export apples and pears the better.

Packing charts are a great help to a packer, and frequent reference should be made to them, especially at the beginning of the season.

The straight pack should be used in preference to the angled pack wherever possible. Pears are packed similarly to apples, but care must be taken not to rest a pear on the stem of a previous one.

A mechanical grader is of great help where fruit is packed on the property, but to get the best out of it care must be taken to have it adjusted correctly. The mechanical grader is a great advantage to the packer who does not have to worry about sizing his fruit. He has also the added advantage of being able to make two packs out of each size of fruit. In a 2½ in. size he can pack the larger apples 150 to the case, and the smaller 165's or 175's, and thus make an excellent pack of the correct height and tightness without any trouble.

USE OF LID PRESS.

The lid press is a great advantage for nailing down, but this can be abused, especially with cases that are packed a little too high. When the press is pushed down the apples of the top layer will frequently be cut on the edge of the case. This can also happen by nailing down in the ordinary way, but not to the same extent. The lid press is quite all right, but it needs care in handling. Cases nailed in the ordinary way should never be attempted without first placing them on battens to allow for the bulge at the bottom.

Wiring is a necessity, especially with the Canadian case. The wire should be put around as close to the cleat as possible, and the tie made on the side of the case, not on the top or bottom, as is sometimes done. In stacking the packed cases, always do so on their side, with the labels facing out.

The fruit should not be kept long after packing, especially in hot sheds, but dispatched to cool stores should there not be a boat available for some time.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

PINNAROO LINE BRANCHES.

The Conference of the Pinnaroo Line Branches was held at Parilla on September 26th, when Mr. H. G. Johnson presided, and Mr. A. J. Cooke (Chairman of the Advisory Board of Agriculture) delivered the opening address. Besides representatives of Branches, the Conference was attended by Messrs. H. B. Barlow (Chief Dairy Instructor), R. C. Scott (Supervisor of Experimental Work), C. F. Anderson (Poultry Expert), R. L. Griffiths (Agricultural Instructor), and H. C. Pritchard (General Secretary). Miss E. Campbell (Inspector of Domestic Arts, Education Department) also attended to give a special address to the members of Women's Branches in the district.

The following papers were read by members of Branches:—"Advantages and Best Methods of Conserving Fodder" (Mr. C. W. Neindorf, Parilla); "Wheat or Meat" (Mr. R. C. Jacob, Geranium); "Poultry Breeding" (Mr. R. Cheney, Parilla); and "Barley Growing" (Mr. H. G. Spratt, Lameroo).

The following resolutions were carried:—(1) That the next Conference be held at Pinnaroo, under the auspices of the Parilla Well Branch. (2) That the present sixpence condemnation levy on pigs be lifted, and twopence in the £ be levied in lieu of same, the money to be collected by the Stud Pig Breeders' Association through stock agents, and paid only on condemned pigs. (3) That this Conference deplores the decision of the Government to remove the facilities which delegates to Congress have enjoyed for so many years in attending Congress, and desires to request that for the benefit of the State in general, and the Agricultural Bureau in particular, such decision be rescinded.

Many questions were submitted to the Conference, and answered by officers of the Department and members of Branches present.

Mr. Cooke presented the trophies to the winners of the 1932-33 District Chandos Wheat Crop Competitions. In making the presentations, he referred to the donation of £100 by the South Australian Farmers' Co-operative Union, Limited, which would be distributed to the various districts throughout the State to assist their competitions this year. Mr. A. J. A. Koch, of Lameroo, who won the trophy for the three-year aggregate, was largely instrumental in obtaining assistance through this channel.

The winners of the competitions were:—First, J. H. & C. H. Spratt, Lameroo (93 points); second, H. E. Angel, Pinnaroo (90½); third, Traeger Bros., Parilla (90); and fourth, C. & L. Fischer, Pinnaroo (89½). Junior Class.—First, Cecil Johnston, Parilla (86½); second, Murray Hutchens, Parilla (83). Highest aggregate in district over three years, 1930, 1931, and 1932.—A. J. A. Koch, Lameroo, with 260 points out of a total of 300. In the Junior Class the highest aggregate was won by Murray Hutchens, Parilla, with 248 points.

In the evening the Conference was addressed by Mr. H. B. Barlow (Chief Dairy Instructor) on "The Pig Industry."

EYRE'S PENINSULA BRANCHES.

Two Conferences were held on Eyre's Peninsula in October, viz., the Southern Districts, at Cummins, on October 4th, and the Central Districts, at Minnipa, on October 6th. Mr. A. J. Cooke (Chairman Advisory Board of Agriculture) delivered the opening address at both Conferences, which were also attended by Messrs. W. J. Spafford (Deputy Director of Agriculture), H. B. Barlow (Chief Dairy Instructor), C. F. Anderson (Poultry Expert), R. H. F. Macindoe (Stock and Brands Department), and H. C. Pritchard (General Secretary Agricultural Bureau), for the purpose of addressing the meetings and assisting in discussions. Messrs. H. D. M. Adams and W. H. Brownrigg (Agricultural Instructors) also attended at Cummins and Minnipa respectively.

THE CUMMINS CONFERENCE.

Mr. G. W. Proctor presided over the Cummins Conference, and papers were submitted by Mr. H. E. Bryant (Cummins), "Fencing"; Mr. M. T. Gardner (Koppio), "Sheep Husbandry"; Mr. E. A. Pfeiffer (Cummins), "The Advantages of Following with a Foot Plough, as Compared with Other Methods"; Mr. R. B. Wilson (Yeelanna), "Methods I Have Found Suitable for Growing Grain on the Lower End of Eyre's Peninsula"; and Mr. F. J. Jericho (Cummins), "Mouse-Proof Haystacks."

"The following resolutions were carried:—(1) That the next Conference be held at Yeelanna. (2) That the Advisory Board of Agriculture again ask superphosphate manufacturers for a reduction of 5 per cent. for cash on super for 1934 delivery. (3) That this Conference requests that farmers be entitled to receive discounts obtained by the State Bank on purchases made on their behalf. (4) That the State Bank Farm Relief Department be asked to endeavor to import cornsacks direct for the coming harvest, to reduce costs to producers working under Farm Relief. (5) That if the Port Lincoln Freezers are sold to a private company that a guarantee be provided that the works shall continue to operate as a freezing works to cater for the farmers on Eyre's Peninsula. (6) That it be a recommendation from this Conference that an inquiry should be held re the price of power kerosene, with a view to obtaining a corresponding reduction in the price, seeing that a big reduction in petrol was made following investigations of the Petrol Commission. (7) That in view of our inability to obtain good roads through the district council, there be a reduction of motor registration on Eyre's Peninsula owing to the bad state of roads. (8) That special Government grants be allotted for making roads in the Cummins-Yeelanna district owing to their shocking state and the great disabilities primary producers have to work under through this cause. (9) That there be a further reduction in rail freights. (10) That the Government be asked to reconsider the decision which removes from delegates to future Congresses the railway concessions, and that such concessions be restored, so that Branches may have an opportunity of sending representatives under the same conditions as in the past.

THE MINNIPA CONFERENCE.

This Conference was presided over by Mr. G. Williams, and a paper was read by Mr. C. A. Newbon (Wudinna), "The Care of Machinery." During the day special addresses were delivered by Messrs. H. B. Barlow on "Marketing the Correct Type of Pig"; C. F. Anderson on "The Poultry Industry"; and R. H. F. Macindoe, "Ailments of Stock." Resolutions were carried as follows:—(1) That the next Conference be held at Kyancutta. (2) That the Government be approached asking that dead-end mains of the Tod River water supply be extended in order to allow farmers to carry more stock, and thus increase the productivity of their farms. (3) That the Railways Commissioner extend the freight concession on one case of fruit to three to five cases, so that Eyre's Peninsula settlers will have an opportunity of buying at rates in comparison with other places in South Australia. This concession will fall in line with the Adelaide Steamship Company's minimum. (4) That a further concession in freight on super be made for the month of February. (5) That this Conference protest against the double exchange on cheques, and urge upon the Advisory Board to make further representations to the associated banks to remove this additional charge. (6) That this Conference urges the Government to immediately resume control of the Minnipa Experimental Farm, with the object of supplying the Eyre's Peninsula farmers with good, clean seed wheat, true to type, and the trying out of new varieties, with a view to ascertaining their suitability to our local conditions. (7) That delegates and Branches have derived great benefits from Congress, and this Conference considers that rail fares should be renewed.

In the evening Mr. Spafford addressed the Conference on "Side-lines on Farms on Eyre's Peninsula."

CONFERENCE OF MURRAY LANDS (EAST) BRANCHES.

Branches of the Agricultural Bureau, situated in the Murray Lands East Districts of the State, held their Annual Conference at Taplan on October 17th, 1933. The attendance was disappointing, delegates being present only from the Loxton, Taplan and Taplan Women's Branches.

Messrs. W. J. Spafford (Deputy Director of Agriculture), C. F. Anderson (Government Poultry Expert), R. L. Griffiths and P. H. Suter (District Instructors), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary Agricultural Bureau) attended on behalf of the Department of Agriculture. Mr. W. J. Hammond (President of the Taplan Branch) occupied the chair, and the opening address was delivered by Mr. Spafford.

Mr. G. Ginner (Loxton) contributed a paper, "Milling Qualities of Wheats," and the following addresses were delivered:—"Side Lines for Mallee Farms," Mr. W. J. Spafford; "Management of the Farm Dairy Cow," Mr. P. H. Suter; and "Diseases of Wheat Crops in the Murray Lands," Mr. R. L. Griffiths.

It was decided that the Advisory Board should decide the place of next Conference, and if possible that the Conference be held during the same week as the Karoonda fixture.

The following resolutions were adopted:—

"That this Conference protests against the action of the Government in deciding not to grant railway fares to delegates to attend the Annual Congress." "That the Taplan Branch express its appreciation of the action of the *Advertiser* in sending a representative to report the proceedings of the Conference."

On behalf of the Advisory Board of Agriculture, Mr. W. J. Spafford presented to Mr. P. R. Hodge, Secretary of the Taplan Branch, a certificate conferring on him life membership of the Agricultural Bureau.

At the evening session, Mr. C. F. Anderson delivered an address, illustrated with lantern slides, "Progress of the Poultry Industry."

CONFERENCE OF NON-IRRIGATED FRUIT-GROWING DISTRICTS.

The Annual Conference of Branches of the Agricultural Bureau in the non-irrigated fruit-growing districts of the State was held at Nuriootpa on November 7th, 1933.

A representative gathering of delegates attended from the Lyndoch, Williamstown, Light's Pass, Greenock, Penwortham, Stanley Flat, Blackwood, Angaston, Watervale, and Balhannah Branches.

Mr. W. Ahrens (Chairman of the Light's Pass Branch) presided and the opening address was delivered by Mr. H. N. Wicks.

Messrs. H. N. Wicks (Member Advisory Board of Agriculture), W. J. Spafford (Deputy Director of Agriculture), G. Quinn (Chief Horticultural Instructor), R. Fowler (Manager Blackwood Orchard), J. B. Harris (District Horticultural Instructor), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary Agricultural Bureau) attended on behalf of the Department of Agriculture.

The following papers were read and discussed:—"Care and Packing of Fresh Fruit," Mr. L. Plush (Light's Pass); "Fruit Drying," Mr. A. J. Chapman (Light's Pass); "Organized Marketing," Mr. D. Farmer.

Mr. J. B. Harris (District Fruit Instructor) addressed the Conference on "Frost Prevention by Orchard Heating."

Mr. K. Robinson (Angaston) reported on the activities of the Frost Combating Committee, and Officers of the Department replied to numerous questions. The evening session was occupied with an address, "With the Trade Ship to the East," by Mr. J. B. Murdoch, of the Advisory Board.

The following resolutions were carried:—"That the 1934 Conference be held at Balhannah;" "That this Conference urges the Federal Government through the State Government to take immediate action in bringing about the control of tree dried fruits;" "That subjects which are of interest to fruit-growers should be given preference over other subjects at all Conferences of fruit-growing Branches."

ADVISORY BOARD OF AGRICULTURE.

The Advisory Board of Agriculture paid a visit to Roseworthy College on October 24th, when there were present Messrs. A. J. Cooke (Chairman), A. M. Dawkins, Dr. A. E. V. Richardson, S. Shepherd, P. J. Baily, F. Coleman, and H. C. Pritchard (Secretary). Apologies were received from Messrs. R. H. Martin, J. W. Sandford, J. B. Murdoch, G. Jeffrey, A. L. McEwin, and Professor Perkins.

Under the guidance of the Principal (Dr. Callaghan), members inspected the Farm, and the experimental work conducted at the College was outlined to them. Speaking on behalf of the members present, the Chairman assured the Principal that they were very pleased with the condition of the farm crops, the fallows, and livestock, and were surprised at the amount of work achieved by Dr. Callaghan since his arrival at Roseworthy.

At a meeting held during the day the following business was transacted:—

Life Members.—The following members of Branches were admitted to Life Membership of the Agricultural Bureau:—M. Reynolds (Narridy) and E. A. Hasting (O'Loughlin).

New Branch.—The formation of a Women's Branch at Balhannah was approved, with the following as foundation members:—Mesdames H. S. Middleton, N. N. Wicks, E. Cox, R. James, F. Norseworthy, F. Leane, B. Spoehr, L. Beckwith, J. Grashy, and Misses D. Spoehr, J. Kelsey, T. Peacock, N. Pitt, D. Camp, and V. Grashy.

South-Eastern Conference.—It was decided to hold the next South-Eastern Conference at Tantanoola.

New Members.—The following names were added to the rolls of existing Branches:—Adelaide—A. Fairbank, H. Fairbank; Appila—E. B. Wurst, E. Shillabeer; Auburn Women's—Mrs. Kench; Barmera—F. Phillips, E. R. Scott; Beetaloo Valley—R. A. Pearce, J. Bugg; Buchanan—J. W. Cuthbertson; Chilpuddie Rock—H. Page; Clarendon—A. Loud; Coonawarra—J. Hinton, jun., P. C. Stafford; Coonawarra Women's—Mrs. W. Pounsett, Mrs. H. Redman, Miss F. Jackson, Miss D. Stafford; Cummins—D. Blacker, H. B. Blacker, F. C. G. Greig; Eurelia—E. A. Wickens, M. Wickens; Jervois—J. Connell, R. Gugtulman, G. Hately, J. Gregory; Kanni—W. Gregory, H. A. Pobke; Ki Ki—A. R. Stevens, C. Stevens, F. Brennan; Kybybolite Women's—Miss D. C. Johnson, Mrs. P. A. Lawrie, Mrs. R. H. Shepherd, Mrs. H. D. McFarlane, Miss E. Glynn, Miss K. Heffernan, Miss M. Moore; Lone Pine—G. Naismith, B. Barrett; Longwood—A. L. Betteridge; Macclesfield—Captain H. G. Hodgson; Maltee—A. L. B. Baasham; McLaren Flat—B. Rake; Millicent—C. G. C. Skeer, R. F. Clifford; Farrell's Flat—G. E. Twelftree; Frayville—E. Hein, L. Hein, H. A. Helbig, E. Bretag; Gawler River—E. W. L. Dawkins; Gladstone Women's—Mrs. Durrant, Mrs. J. A. Flavel; Hanson—Sergt. G. McDonald; Hope Forest—S. H. Reed; Murray Bridge—C. S. R. Whitbread, G. Riches; Nelshaby—S. Thomas, T. Davies; Nelshaby Women's—Mrs. L. Lane, Miss L. Lane, Miss D. Jose, Mrs. Pearce; Owen—J. Davies; Palalie—R. Mullins, W. Sheedy, R. M. Hamilton, R. Sheedy, H. Bates, N. Rashleigh, W. Miller, jun.; Parilla—L. G. Wright, S. R. G. Cheney; Parilla Women's—Mrs. S. R. G. Cheney; Moorlands—J. Peitsch; Mount Barker—Major Irwin, J. L. Turnbull, W. Slade, N. Alcock; Mundalla—H. Hillier, K. Hillier, G. Hillier, I. Dinning, R. Packer, H. Donnell; Mundalla Women's—Miss M. Knowling, Miss C. Hinge; Bendelsham Women's—Mrs. C. Buhlman, Miss D. Buhlman, Mrs. W. McArthur, Miss M. McArthur; Saddleworth—E. Saint, W. Vogt, B. Ashton, L. Dungey; Scott's Bottom—A. J. Martin; Shoal Bay—W. W. Cook; Stanley Flat—W. Moore, R. Lang-

ridge; Strathalbyn—V. C. Ellery, E. A. Stacey, A. P. Saunders; Sutherlands—J. Sander, B. Doecke; Taragoro—E. Benson; Paruna—N. L. Haines; Paskeville—C. K. Stephenson; Penola Women's—Miss M. Reschke, Mrs. R. Balnaves, Mrs. J. W. Anderson, Mrs. A. W. Pearson, Mrs. J. Hall, jun., Mrs. C. Neilson, Miss I. Neilson; Penwortham—H. J. Hudson, N. Hudson; Pinbong—A. E. Cheaney, L. Kammermann, H. Scholz, D. Scholz; Pygery Women's—Miss M. Kammermann; Ramco—A. E. Seary; Redhill—R. Crouch; Rendelsham—C. Osmond, J. O'Toole; Tatiara—M. Dodd; Tintinara—D. L. Jones, L. F. Galley; Warcowie—L. Lipert, R. Felten, C. Wheaton, L. D. Sweet, L. J. Carpenter; Warrambo—C. Sampson; Wasleys Women's—Miss G. Smith; Wepowic—H. W. Noske, J. M. Jasper; Wudinna—J. Browne, E. Browne; Yeelanna—R. Watkins; Petina—F. Daniels—Taplan Women's—Mrs. B. Eime, Mrs. P. Condon; Nunkeri—R. Grills; Coonawarra—R. J. Skinner.

Other items were taken in Committee.

DAIRY AND FARM PRODUCE MARKETS.

MESSRS. A. W. SANDFORD & CO., LIMITED, reported on November 1st, 1933:—

BUTTER.—Production is now cutting back considerably owing to the incoming of hot weather at the end of October which wilted off the feed in many districts, and supplies have therefore cut off more quickly than was anticipated. Unfortunately the London market, just as production was at peak, became somewhat demoralised, and owing to the Commonwealth Control Board having fixed minimum prices above what London merchants were prepared to operate at, heavy quantities went forward from this State on consignment. These shipments, unfortunately, will arrive at drooping markets, so that considerable losses seem likely to be incurred. On account of this an adjustment of butter fat values became necessary, but it is to be hoped that some interest will be shown in Australian butter with the easing in prices through the greater consumption which usually follows when the commodity is selling at more moderate rates. The local prices remain unaltered. Choiceest creamery fresh butter in bulk, 1s. 0½d. Prints and delivery extra. (These prices are subject to the stabilization levies.) Store and collectors', 4½d. to 5d. per lb. at store door, less usual selling charges.

EGGS.—The usual seasonal decrease in supplies is now in evidence, brought about by the drying off of the feed in most areas. Unfortunately also the proportion of eggs which would pass the Commonwealth graders are lower just now because of the warm weather, so that the quantities packed for export will from this out decline. Values are unchanged. Ordinary country eggs, hen or duck, 4½d. per dozen; selected, export quality eggs, 1½ozs. and over, 8½d. to 9d. per dozen.

CHEESE.—The outlook for the production of cheese is not nearly so bright as compared with a month ago, for the hot weather materially affected the supplies, so that the quantities to be exported will not be nearly so great as last season. Prices for cheese have maintained, and local and Western Australian trade kept well up to the average. New makes, medium and large, 7½d. to 7¾d.; loaf, 7½d. to 8½d.; semi-matured and matured, 9½d. to 10d. per lb.

BACON.—As usual during the hot period of the year, the consumption of bacon falls and there has been since the opening of the month less sales for certain cuts of bacon than was previously the case. On the other hand, however, hams are selling more freely, and also bacon factory smallgoods. In anticipation of larger sales with the nearer approach of Christmas, curers have been kept working at high pressure, and as the quality of the established brands of bacon has been well maintained, the outlook is satisfactory. Best local sides, 9¾d. to 9½d.; best factory cured middles, 10½d. to 11d.; large, 9d.; rolls, 8d. to 8½d. Hams, 11½d. to 1s. 0½d. per lb.; cooked, 1s. 2d. to 1s. 2½d. Lard, prints, 7s. per dozen.

LARD.—Supplies have been a little more plentiful, so that some interstate trade was possible during the last few weeks.

ALMONDS.—Quantities marketed during the last few weeks have only been limited and these met with ready sale, as some of the larger storekeepers purchased supplies for their Christmas trade, and still need further lots. It is therefore anticipated that strong demand will continue, although there is no firming in rates. Kernels were also taken up readily at quotations. Softshells and Brandis, 8½d. to 9½d.; hardshells, 5d. to 5½d. per lb.; kernels, 1s. 11d. to 1s. 1½d. per lb.

HONEY.—For the prime clear extracted consignments of new season's, good demand was experienced last month, but the quantities marketed have not been great. Lower grades of dark and inferior sorts were very difficult to quit. Prime clear extracted in liquid condition, 3d. to 3½d. per lb.; lower grades, 1½d. to 2½d. per lb.

BEEWAX continues to meet with ready sale where the quality is right; 1s. 0½d. to 1s. 2d. per lb. according to sample.

LIVE POULTRY.—The catalogues submitted recently have not been sufficient for the requirements of the trade, especially as some poulterers already have commenced putting supplies away in refrigerators for their Christmas requirements. Consignors would be well advised not to delay the forwarding of their surplus stock until too close up to Christmas, when the markets become somewhat over-supplied, but to forward any birds they have ready straight away. Crates loaned on application. Prime roosters, 3s. 3d. to 4s. 6d.; nice conditioned cockerels, 2s. 8d. to 3s. 2d.; fair conditioned cockerels, 2s. 5d. to 2s. 8d.; chickens lower. Heavy weight hens, 2s. 3d. to 3s. 3d.; medium hens, 1s. 10d. to 2s. 2d.; light hens, 1s. 5d. to 1s. 9d.; couple of pens of weedy sorts lower. Geese, 3s. 6d. to 4s. 6d.; goslings lower. Prime young Muscovy drakes, 5s. to 6s.; young Muscovy ducks, 2s. 10d. to 3s. 8d.; ordinary ducks, 1s. 9d. to 2s. 6d.; ducklings lower. Turkeys, good to prime condition, 10d. to 1s. 1d. per lb. live weight; do., fair condition, 7d. to 9d. per lb. live weight; do., poor and crooked breasted, lower. Pigeons, 4½d. to 5d. each.

POTATOES.—Old, 4s. 6d. per cwt.

ONIONS.—Old Brown, 4s. per cwt.

RAINFALL TABLE.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[Branch Secretaries are reminded that the following are exempt from payment of the Annual Bureau subscription:—Life members, Branch Secretaries, members appointed before August 1st, 1930, and new members who reside in the same house as (a) a life member, (b) Secretary, or (c) another member who already subscribes.

The subscription for all other members is 2s. 6d., commencing from August 1st in each year, provided that—subject to the above exemptions—nominations forwarded during the months of January to June must be accompanied by a payment of 1s. 6d. each nomination for that period.]

UPPER NORTH DISTRICT. (PETERBOROUGH AND NORTHWARD.)

APPILA (Average annual rainfall, 14.69in.).

August 8th.—Attendance, 11.

FARM CONVENIENCES.—Mr. C. Borgas read the following paper:—"Conveniences on the farm result in the saving of much time and labor. A gate made from pipe or iron, and fastened to a good stout post by means of hinges so that it swings without having to carry it, will prove very useful. A gate with a bolt latch should be swung so that a person has to lift it, say, $\frac{1}{2}$ in. or $\frac{3}{4}$ in., to hold the latch tight. A strong wind has a tendency to shake the gate, and in time the latch works its way out of the hole in the post and the gate swings open. Another good convenience is the motor ramp, which should be constructed of strong material, such as three main beams of 'I' iron, 8 in. x $\frac{1}{2}$ in. x $\frac{1}{2}$ in. The cross pieces from old railway or tram rails can be bought very reasonably, and will make an everlasting ramp. The ramp should be built on concrete walls, and made 6 in. to 1 ft. above the surface, with a pit 3 ft. deep. Every motorist should have a set of chains to use if the car becomes bogged. A serviceable set can be made from pieces of chain about 9 in. long and harness straps. The chains can be made from old harvester chains which have become useless. If the links are badly worn they should be closed down." Discussion:—A few members did not agree with the writer regarding the lifting of the gate to unlatch. For small children it would be inconvenient, and nearly every swing gate will sag down in time, and the latch will then be tight. A small hook around the latch handle is quite effective in keeping the latch in place. (Secretary, E. Wurst.)

MIDDLE-NORTH DISTRICT.**(PETERBOROUGH TO FARRELL'S FLAT.)**

BLYTH (Average annual rainfall, 16.77in.).

July 28th.—Attendance, 19.

FALLOWING.—Mr. E. Eime read the following paper:—"As a general rule, provided it receives good after treatment, the best and most profitable fallow is that which is ploughed earliest in the season. The main advantage of early fallowing is that it enables the farmer to more thoroughly store up winter rains by exposing soil with a loose, broken surface, and secondly, under the influence of rain, it permits of the under-surface becoming consolidated to a suitable degree. In some soils it is not advisable to plough too early, because the land is beaten down by early winter rains, and tends to set harder than if it had not been ploughed at all. Such land should be left until later in winter. If one has both light and heavy land to work, break up the lighter land first, because if left until late it may not become consolidated sufficiently before seeding. In this district fallowing should start as soon after seeding as possible—June, July, and possibly August being the best months. Later fallow remains too open to make a suitable seed bed. In districts where late spring and early summer rains are frequent, fallowing may be continued until later in the year. Everything depends upon the quantity of rain the ploughed land is likely to receive before seeding. A great deal of difference of opinion exists on the depth to plough. The great bulk of South Australian fallowing is shallow, from 2in. to 4in., and has given satisfactory results. Shallow ploughing has the advantage of being economical in horsepower. Whenever compelled to fallow late, plough very shallow, in order to make consolidation easier. The plough used should possess well-shaped mouldboards, that will turn the ground over properly. The shares should be kept in good condition, and the furrows evenly spaced. Care should be taken to leave no strips between the furrows. When ploughing sandy soil that is likely to drift, a disc plough is very useful, because the straw can be turned under to prevent drifting. Many farmers use cultivators for breaking up the land. This may be all right where there are no weeds, and the ground is not too hard, but if the ground be very 'green,' it may not be any cheaper in the end, for it will probably need more working back if weeds are not turned under. The land should be harrowed to pull it to pieces, and if it is not properly broken up then a second harrowing is necessary. Sandy ground should not be harrowed. It causes a lot of drifting, and it sets down better if not disturbed too much. Cultivating should be left until the end of September or October, when such should be done to destroy weeds. The first cultivating should be about the same depth as ploughing, and the rest of the cultivating should gradually get shallower. The fallow should be worked after every heavy autumn rain, when weeds appear. Cross working is advisable, it gives a more even cultivation of the soil. The fallow should be cultivated again soon before seeding. It kills a number of weeds and makes a finer seed bed." (Secretary, R. Eime.)

TRAINING A DOG.—The following notes are from a lecture delivered by Mr. A. Semmler:—Do not start training a dog too young; it should be about six months old before it is used for horses and cattle, but a sheep dog can be educated earlier. If children are permitted to play with young dogs they do not work so well. I prefer a dog that barks to a silent heeler; they shift cattle and horses better. To get a good cattle dog cross a silent heeler with a dog that barks. A dog should be trained to work by signs of the hand, because often it is not possible to speak to a dog when it is far away, or on a windy day. Cattle dogs are very useful for rabbiting. When choosing a dog for hunting see that it has plenty of lung space. When a young dog catches its first rabbit or hare only give it the lungs to eat. (Secretary, F. Roocke.)

BUCHANAN.

July 7th.—Attendance, 11.

ROTATION CROPPING AND SIDELINES.—Mr. J. Armstrong read the following paper:—“During the past five years the whole of the farming industry has been practically revolutionised by the fall in the price of farm products. How much better off to-day would the farmer have been if he had organised his sidelines on a sound basis in prosperous times? The slump in both wheat and wool would never have hit him so hard. It is only by getting back to sidelines that we are likely to retrieve our position. Most of the farms in the district are about 400 acres in area, and the general practice is wheat-fallow alternately. It is possible that in this rotation the land will become wheat sick, and returns greatly reduced. My experience has led me to believe this: some method other than wheat-growing alone must be introduced. On my farm I have endeavored to spell land to grass as much as possible to try and keep the land in good heart for wheat, but the farm is hardly large enough for the purpose, and by introducing a system of rotation of oats on stubble land better results could be obtained in the carrying of more dairy cows without curtailing the sheep flock. This system should give a much bigger percentage of hay, besides a larger supply of grain for the lean months, and also place the land in good condition for wheat again. Being within 70 miles of the Abattoirs, the road service excellent, and also a good train service, the district is extremely well provided with transport. Dairying carried on in conjunction with pig raising would be a big advantage to the small farmer in this district, instead of wheat alone. Pigs can be raised far cheaper by running in a paddock to graze at will in preference to shut up in the sty. Much discussion is going on over which breed is most suitable for export, and until one class of boar is supplied to the breeder at a reasonable figure nothing in the way of a uniform carcass will be obtained for export. Where the area of farms is larger, sheep can be kept with much better advantage, but the growing of more oats will increase the carrying capacity and provide for lean times.” (Secretary, L. Bell.)

LIGHT'S PASS.

July 31st.—Present: 28 members.

GRAFTING VINES.—Mr. W. Ahrens read the following paper:—“When contemplating grafting, first make sure that you are converting to a variety which will always command a ready sale. Procure your scions of the favored variety, this should be done as soon as possible after pruning. The cuttings should not be too thick, and cut into convenient lengths, say 2ft., tied into small bundles, wrapped in a bag, and buried in a moist but well-drained place—deep sand for preference—until required. Time of grafting is governed chiefly by the season and soil conditions, nothing will upset the graft so easily as excessive moisture. Should the season be dry, and the soil well-drained, the latter half of September would be a good time to graft. However, in soils that are at all inclined to become waterlogged, wait until about the middle of October, by this time the heavy rains have generally ceased. The land should be well cultivated prior to grafting, so that plenty of loose soil will be available for packing around the graft. At one time the popular idea was to graft just beneath the surface, and not allow the graft to make any roots of its own. I favor grafting at least 6ins. beneath the surface, and permit the graft to retain its own roots, which makes very strong growth the first season, and after a few years the graft becomes practically independent of the old stock, and any danger which may exist from lack of affinity between stock and scion is therefore reduced to a minimum. Another advantage of deep grafting is that in some cases, although the graft comes away fairly well—the union is not perfect, and in such cases the graft will thrive much better if allowed to retain

its own roots. Here again it must be remembered that the danger from excessive moisture is far greater with deep than shallow grafting. The tools required are a spade, saw, knife, grafting tool, mallet, and billican. Enough scions for half a day's grafting may be cut ready before starting, and carried in the 'billy' which must be about half filled with water. The soil is removed from around the vine to the desired depth, the vine sawn off, and grafted. As soon as the operation is completed, a few handfuls of soil should be packed tightly around the graft, it can then be left for half a day if necessary before filling in the hole. When filling in, the soil should be thrown against the sides of the hole, away from the graft first, and it will be found that one shovelful around the graft will complete the job without much danger of dislodging the scion. Next drive in a stake alongside each graft—if a trellis is already erected, a thin bamboo will do—but the top must be tied to the wire. When the young shoot has reached a point about half way between the ground and the wire, the tip should be pinched out, it will then throw out two laterals of even strength, and a nicely balanced vine will result. It will be necessary to go through the plot occasionally to remove any suckers that may be coming through from the old stock. Any time spent in training the young vine during the first season's growth will not be wasted, a good foundation will make for easier pruning in future years. *Affinity of Stock and Scion*—Much remains to be done in this direction, and our knowledge to date is very limited. Shiraz does not do so well on any foreign stock as on its own roots, whereas the currant seems to thrive on any stock. Never graft onto Sercial, for this variety has a very poor root system, if it must be replaced, it is better to grub and replant. It is a debatable point whether it is advisable to graft very old vines of any variety, for anyone who can possibly afford it, grubbing and replanting are more satisfactory. Mr. Ahrens illustrated his remarks with black-board illustrations. (Secretary, C. Verran.)

FIELD DAY AT LONE PINE.

In an effort to stimulate interest in Agricultural Bureau activities, the Lone Pine Branch held its first Field Day on Monday, October 30th.

Thirty members and a fair number of visitors, including Messrs. W. J. Spafford (Deputy-Director of Agriculture) and F. C. Richards (Assistant Secretary of the Agricultural Bureau) made a tour of the Lone Pine (Tanunda) district. The party met at Mr. F. Fromm's property, and found him busy dipping sheep. This dip performs a community service, and adjacent landholders are charged a nominal fee for putting their sheep through. This year he expects that 1,500 sheep will be dipped. Many of the visitors were surprised when Mr. Spafford informed them that the dipping of all sheep in the Tanunda district was compulsory.

When Mr. Fromm took over his present property four years ago the fences were in a shocking condition. These have all been made sheep-proof, and a 10,000-gallon cement tank has been erected on top of rising ground, from which water is reticulated to each of the 11 paddocks into which the holding is divided. The property consists of 200 acres, 25 acres being devoted to vines, and 50 acres this year have been sown with wheat and oats, which are to be cut for hay for hand-feeding to sheep.

TOP-DRESSING COMMENDED.

Mr. Fromm is a strong advocate of the value of top dressing, and has applied superphosphate to 15 acres, at the rate of 2cwts. to the acre. His flock numbers 200, and consists of Dorset Horn and English Leicester crossbred ewes and Merino ewes. He is building up his flock on sound lines, and is using as sires six Dorset Horn rams from Mr. W. J. Dawkins's "Newbold" stud. He also purchased three stud ewes from the same breeder. The flock is run with the main object of providing fat lambs for the local trade, the butchers purchasing from the stock on the farm. This season his lambs averaged 15s. 6d. per head.

To provide a green picking for his top sheep, Mr. Fromm has set aside five acres, which will be sown with lucerne and Sudan grass, and irrigated.

FROST DAMAGE.

The next property visited was that of the President (Mr. Ben. Fromm). Here those members of the party who had not previously seen what frost can do to a vineyard had brought home to them what the visitation of the previous week had done to some portions of the Barossa district. Mr. Fromm has 20 acres under vines, and almost every vine has been cut back to the canes. The foliage appears just as though it had been scorched with fire, and the whole vineyard was black. Mr. Fromm said, "I will be lucky if I pick a bunch of grapes this year."

Mr. Fromm's chief sideline is poultry. He has 500 White Leghorns, and is marketing three cases of eggs each week. From these he averages only about a dozen rejects, proving that he realises the importance of quality and size of egg. The birds are housed in good sheds, but the general opinion of those who inspected them was that not

sufficient provision had been made for light to enter the houses, and that the birds would benefit by the addition of minerals to the feeding ration. A home-made 300-capacity brooder (battery) created much interest.

On Mr. C. F. Beckmann's farm portion of a paddock of 80 acres was sown with oats and Le Hugenot wheat for hay, and was expected to cut two and a half tons to the acre. A small area was under barley, and Correll's, Waratah, and Sepoy wheats were sown over the balance of the paddock, the better portion of the wheat giving indications of a good yield. The whole of the paddock was fed off during the early stages of the growth of the crops, and carried 220 sheep for eight weeks, the lambs, when three months old, realising 16s. 6d. per head.

WINE CELLARS INSPECTED.

The Wonganella cellars and vineyards of Messrs. F. W. Fromm & Sons were next inspected. Here the greater portion of the vines appeared to have escaped the frost, but those planted in the lower situations of the vineyard had been caught. The cellars have a capacity of 60,000 gallons, the greater bulk of which is stored in underground cement tanks, and the plant is capable of handling each year 300 tons of grapes. By far the greater part of the wine is sold for home consumption. The party was very interested in a well which had been sunk through 35 feet of solid rock, and provides an excellent supply of first-class water.

Two of the best crops of wheat inspected during the day were King's White and Nabawa, on the property of Mr. E. R. Hentschke. These were estimated to yield 30 bushels to the acre. Mr. Hentschke has an enviable reputation as a wheatgrower, and has a ready sale for his grain as seed wheat.

The party was entertained at afternoon tea at the Wonganella Cellars.

CARE OF BREEDING STOCK.—Paper presented by Mr. T. Rodda:—"During this period of low prices and depression it is necessary to take great care of breeding stock. The horse is recognised as the most important animal in our immediate district. *Mating Season.*—The year with this stock commences from the 1st of August, which is the general month for the commencement of the breeding season. If keeping a sire, see that he is in the pink of condition—not overfat but in good, hard condition. If seeking a sire for mares, see that the horse has breeding and quality with plenty of life and a good temper. A good plan is to watch a neighbor's teams and young stock; this will prove a guide to a suitable horse. Mares at this time of the year should be in good condition—one that is overfat is not usually a good breeder. If a mare has been worked down during seeding and is showing a worn-out appearance, it is wise to let her rest until later in the spring. After service, leave the mare 21 days before bringing her to the horse again. The usual time of bringing a wet mare to the horse is on the ninth day; always try to catch a wet mare during her first heat period after foaling. *In Foal Period.*—Great care should be taken during this period. The mare should not be over-worked, but must have plenty of exercise; ordinary farm work is one of the best forms of exercise, and is most beneficial. Lump rock salt for lick is a good tonic. If constipation arises, violently acting medicines must be avoided; it must be corrected by an easy laxative such as oil or some other equally soothing agent. In the later stages a mare should not be frightened nor teased by other horses so that they kick out suddenly, or abortion is likely to occur. *Natural Foaling.*—As the time of foaling approaches, the swelling of the udder indicates the coming event, in some cases the swelling extends to the abdomen and even into the hind limbs. Discharges appear of a whitish character from the teats. It is wise when a mare reaches this stage to watch her at intervals, night and day. For convenience she should be kept in a small paddock close to the house. When the mare becomes uneasy and has an anxious expression, she should be watched closely. The water-bag appears and breaks, followed by the front feet of the foal with its nose between the knees; with a little more labor the foal is born, the navel string becomes broken, and in a few minutes the membranes are expelled. A little later the mare generally cleans the foal by licking it all over. The whole act may not take 10 minutes, so that the foaling is often not seen. *Treatment after Foaling.*—It is a good plan to give the mare a warm bran mash and leave her alone, visiting her occasionally to see how she is getting on. If there is any difficulty in getting the foal to suck, a good clean out with warm soapy water is advisable. Perhaps one of the greatest troubles that a horse breeder finds is retention of after-birth. It is said that three times as many mares die from this than all other complications of foaling. Not a particle of after-birth must be allowed to remain in the mare after a few hours of foaling, as it speedily decomposes, setting up inflammation and causing septic poisoning. There are different methods of removing it—by gently twisting it around like a piece of rope and gradually pulling until it comes away, or by affixing a weight; when the latter method is used be sure that it has come away clean. If after-birth is retained for any length of time always give the mare a few injections of warm water to which has been added a few grains of Condly's crystals. *Cattle.* *Mating Season.*—Keep the bull in good healthy condition and away from the cows during the mating season. If a cow is hard to stint she should be given a good laxative two or three days before the heat period is expected. *In Calf Period.*—Cows during this period should be well fed and cared for. There is a big drain on the system, as usually the cow is milking. It is unwise to make the cows run or to use a rough dog. The quieter they are handled the better the result at all times. Keep salt and super in the cowyard, and if necessary, give it with the feed two or three times a week. *Natural Calving.*—If cows are showing signs of constipation prior to calving, administer a laxative. The correct position of the calf for natural calving is the same as with a foal. Care should be taken to see that no after-birth remains; also, give a laxative. *Sheep.* *Mating.*—The main point is to so arrange the mating that lambs are dropped at a time of the year when feed is plentiful. As soon as a young lamb requires more than its mother's milk it must have good, succulent pastures. Therefore, the lambing time selected must be such that there is prospect of four or five months of good grazing ahead. Lambs from Merino ewes do not do well when dropped in cold weather; I prefer them dropped towards the end of autumn or early winter. At this time the weather is milder and the lambs become strong before the cold, bleak conditions. The average gestation period is 150 days, and therefore it will be necessary to mate about five months before the time desired for the first lambs to be dropped. The rams should be strong and healthy. If either too fat or too low in condition the result is not likely to prove satisfactory. When mating for fat lambs, the number of rams should not be limited, and if possible, more than one should be turned in with the ewes, as

they then work better than if alone. In ordinary circumstances not more than 50 ewes should be mated to 1 ram. Shearing and dipping check the desire to mate, and therefore these operations should be carried out at least a fortnight before joining with the ewes. The rams may be allowed to remain with the ewes from 8 to 10 weeks. The ewe should not be too old; never use broken-mouthed ewes if possible to get others. Ewes should go to the ram in good store condition and be maintained in this state during the whole of the gestation period. *Lambing.*—If feed gets short in autumn, the flock must be hand-fed. As lambing approaches, a good sheltered paddock should be reserved for the lambing flock. The lamb is a source of revenue, and close attention must be given to the flock; during lambing it should be visited once a day. On the completion of lambing a good plan is to remove all dry ewes. Tailing and castrating should be done when the lambs are from 2 to 3 weeks old. At this age they suffer less shock and recover more quickly than when older. Remember that cleanliness is essential in this operation." (Secretary, S. Chynoweth.)

SOUTH KILKERRAN.

August 1st.—Attendance, 11.

FARM MACHINERY.—Mr. L. Jacka read the following paper:—"There are five essential points in the care of farm machinery, namely, adjustment and repairs, lubrication, careful handling, protection from weather, and a coat of paint occasionally. One of the best ways of reducing machinery costs is by systematic and efficient repairs. Another most important point in repairing farm machinery is to do it regularly before the machines are put away. The value of keeping a machine in order ready to start at any time cannot be over-estimated. Before starting any machine—especially a combine or a binder—see that every part is well adjusted. All nuts should be tightened, especially on a new machine that has been in use for two or three days. All worn parts should be replaced before putting a machine away, and when replacing a bolt see that it fits the hole correctly, never put in a bolt that only partly fills the bolt hole. Repair the machines before putting them away, when the condition of the machine is quite fresh in the operator's mind. The combine should be well cleaned out, and the super stars given a coat of blacklead. This keeps them from rusting and becoming stuck; the wheat side should be given a wash out with kerosene to prevent the cups from sticking. The rubber hose should not be put in the box and left until next season. A much better plan is to thread them on a wire and hang them in a dry shed so that they will hang straight down. Stored in this way, they never become kinked or bent. Before starting any machine it is essential to oil all working parts with kerosene and oil, and see that all parts work freely. Proper attention to lubrication and a few extra shillings spent on oil will prove a good investment. Lower costs and better work will come from machines given proper attention with oil and grease. Poor oil and grease, or not enough of either, will result in unnecessary expense in repairing parts. The life of the machine is often shortened by rough handling. When a machine is finished with it should be put away in a dry shed. Left out in the weather, it is damaged by heat and rain, and this very often takes more off its appearance than the actual work. A lot of machinery is used only six or eight weeks in the year, and in some cases is left out in the open twice as long. The wearing parts become stiff and rusted, and the woodwork very dry. A machine treated in this way very soon has a second-hand appearance. It is possible to get long service out of a machine only when it has proper attention. Implements such as harrows, ploughs, and cultivators, can be left in the open, but should be given a coat of paint every three or four years. Paint adds years of life to the wooden parts of the machinery." (Secretary, R. Hastings.)

GREEN PATCH (Average annual rainfall, 26.56in.).

July 6th.—Attendance, 9.

RELATIVE VALUE OF BIRD LIFE AND TREES TO SUCCESSFUL AGRICULTURE.—Mr. L. Derrington read the following paper:—“When considering the successful pursuit of agriculture generally, one is often likely to forget the economic value of these two phases of natural life to farming, either cereal or orchard. Both birds and trees should be taken into serious consideration. Either from a sporting aspect or purely defensive view, it does not always seem wise to destroy our natural bird life, or denude the country of all big timber in our efforts to open up and farm the country. The destruction of most vegetation, crops, and orchards would eventuate, except for the ceaseless attacks of the birds of many varieties, on the almost limitless army of insects, grubs, &c., which prey on all plant life, generally to our loss. For instance, the potato beetle is capable of reproducing 60 million offspring in a single season. The common plant louse produces living young; having a short life cycle, they have 13 generations in a single season, each female producing, on the average, 50 young. These are examples of how insect life multiplies, and would devastate the whole country if there were not bird life to help keep this enemy within bounds. Viewed through powerful glasses, scientists have proved that certain birds consume enormous numbers of insects annually which are injurious to crops and vegetation generally. For example, the scarlet tanager has been observed, by very careful watching, to consume 630 caterpillars in 18 minutes, and 3,500 plant lice in 40 minutes. Great tits have been known to visit apple trees 47 times picking off caterpillars. By such unobtrusive means are our efforts to produce grain and fruit, &c., helped to success of varying degree. The common sparrow, often harmful because of the amount of grain it takes or damage to fruit, still does a lot of good when feeding its young on caterpillars and grubs, and so one might continue in the same strain in regard to the majority of our native birds. So it would seem that, although certain varieties appear to be a pest in certain respects, they probably do more good than harm in helping the agriculturist to attain his ends. It is stated on good authority that flights of owls generally follow a plague of field mice, these rodents being their particular diet. Opinions will vary, probably, as to the good or bad qualities of many of our feathered tribe. The common crow—although a pest of the first degree in many respects, chiefly with regard to lambs—still does a considerable amount of good as a scavenger and grub eater. Our Australian cockatoo, a rare pest at seeding time and harvest, particularly in the northern areas, does good in consuming the seeds of noxious weeds. In regard to tree life in relation to agriculture, big timber carrying a wealth of foliage is a great asset to successful agriculture. The roots of the big timber reach down to great depths after moisture, bringing this up through their roots, trunk, and on up to the foliage, from which the tree gives forth great quantities of this moisture via the air, benefiting surrounding country. The fallen leaves through the centuries make some of the richest soil. The opening up of and reclaiming of large tracts of land in many parts means the destruction of tremendous quantities of big growing timber, and although this practice is necessary to a certain degree, it seems that the denuding of the country is rather overdone in many instances. Deforested regions visited by torrential rains and floods tend to become desert, and in places drift to a considerable extent. The less tree life, the less moisture retained in the soil. The harm of ruthless destruction of forests in all parts of the world has long been felt, and the problem has been studied in many continents. Steps have been taken to remedy the loss caused by the above practice, either by reserving certain forest areas or by replanting large acreages with varieties of young trees, and help fill some of the gap that industry has created. Often some of our rough and rather poor soils have been turned to profitable account by planting in such manner. Germany was among the first to realise the economic value of following the above principle. In our own continent better farming results would be obtained if more and possibly wider timber breaks were left on a block when clearing preparatory to commencement of a farm. This naturally applies more to the drier and sandy localities of Australia's farming areas.” (Secretary, C. Whillas, Port Lincoln.)

KOPPIO (Average annual rainfall, 22.40in.).

June 27th.—Attendance, 18.

SHEEP AND WOOL.—Mr. C. Goddard (Assistant Wool Instructor of the School of Mines), in an address on this subject, said sheep must be of good type before a good type of wool could be grown. In many cases the quality of sheep on farms was not good enough, and the pooriness of type of wool made the keeping of such sheep unprofitable. The Merino was the best wool type for Eyre Peninsula. There was vast differences in types, and the most profitable type was the important fact to consider. The individual types of wool were fine, medium, and strong. Strong wool would yield 2lbs. more than medium, and 4lbs. more than fine per fleece. He was an advocate for

medium strong wool, but it must show quality. This type of wool filled more bales, and in turn enriched the grower to a greater extent. The narrow-chested, wrinkled, fine Merino could be discarded, and the stronger and more robust type grown. The strong type of wool grew on strong-constituted sheep, as was demonstrated by the sheep grown on outside pastoral country. In some localities the medium, fine-wooled sheep died in times of drought and the strong wools lived. The sheep's constitution was a big factor in economical sheep husbandry. The medium and fine types did well on good grassland, but the cutting capacity was 2lbs. less than the big framed, strong type, and this extra wool at 1d. per pound less meant from 1s. to 2s. per sheep. The strong wool ewe produced an earlier maturing lamb, which grew to greater carcass weight of 6lbs. to 10lbs., hence the aggregate advantages over the medium and fine go to the strong wool. The finer types were more prone to attack from blowfly than the medium strong type. In breeding medium strong-wooled sheep owners must pay special attention to selection of suitable rams to prevent the wool from becoming daggy around the breech and to maintain a high standard of quality in the wool. Sheep must have plenty of feed to produce wool profitably—300 sheep well fed were better than 500 indifferently fed. Feed counted for 90 per cent. of sheep management. All flockowners should have

DELIVERY.—CHICKS—February and March.
EGGS—January and February.

Intending breeders should recognise the importance of establishing their flocks with only the very best of stock also, pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2ozs., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

a reserve of feed and, if necessary, handfeed over lean periods. Starvation—even for a short time—showed in wool, and weakness in the fibres known as tender wool was the result, therefore feeding over lean periods paid with better grown and better nourished fleeces. *Marketing and Valuing Wool.*—Different buyers from different countries valued the wool with limits, and formed an idea of value on “tops”—wool sorted, scoured, carded, and combed. Valuation was an intricate and expert job. Often farmers stated that wool was worth so much per pound and would not sell for less than the estimated value, but how does the farmer know the value of wool? Mr. Goddard recommended the selling of wool as soon as it was sent to market. Every quality of wool had a type value. All wool should be graded, and graded with systematic practice. The reputation for good wool built up by Australian woolgrowers was now waning. For instance, an estate 30 years ago grew 1,800 bales of wool of one quality; now the same estate cut up into farms probably grey 2,000 bales of farmers’ lots of wool from different types of sheep and marketed in a mixed state. Experts stated that by this mixture of types of wool in the bales farmers were losing £1 per bale by not classing their clips. New South Wales had 260,000 bales of unclassified wool, and South Australia 50,000, or 25 per cent. of the wool output. Growers might be content to lose £1 per bale, but the national outlook had to be considered. Buyers had passed a resolution that every bale of farmers’ wool must be shown on the show floor, hence the cost of selling would be doubled, and growers would have to pay for the trouble. Farmers’ wool was often sold to dealers for less than its value, because it was not properly graded and marketed. The following were some of the main advantages of classing wool:—To make maximum profits out of the clip; to class in such a way as to suit customers; and to meet the requirements of buyers. Why classing of wool was necessary:—Sheep did not produce wool even enough in type or quality and utility for all purposes; fleeces differed in parts, and value in parts differed. That difference was the basis of wool classing. When the fleece was picked from the shearing floor a rolling table was necessary 10ft. x 5ft. and 3ft. 6in. high so constructed that small particles of wool would fall through and that could be walked around when skirting and taking off inferior edges. Types of wool were valued differently. Over skirting degraded certain values. When the value for pieces was nearly as much as fleece wool it showed over skirting. In classing small clips the same keen attention should be given as with big clips. Different out-type fleeces, such as extra short, extra heavy, extra strong, and yellow fleeces should be left out of bales with uniform type of wool, and put in with part bales of bellies, locks, lambs, &c., and separated with a small division of hessian and marked outside the bale as well. In this way freight and charges could be saved. Any such mixed bale was drafted to the bag pool, sorted and classed, and each type was accorded its type value. A reference list of each bale should be sent to the broker when wool was forwarded, and a letter sent giving full particulars of each and every bale; then each bale could be treated accordingly, and the highest value obtained for it. Wool being a valuable commodity it was worthy of good packing, and the neatness and attractiveness of the get-up of the clip was in favor of the grower. Mr. Goddard, in reply to a question, stated that the most practical way to start to strengthen up the quality of the wool was to secure good quality strong wool rams of 58’s-60’s count from a well established breeder, and keep on getting the same type of rams from the same breeder. (Secretary, M. Gardner.)

KYANCUTTA.

July 4th.—Attendance, 112.

FALLOWING.—The following papers were read on this subject by Messrs. T. Holman, E. Kelly, and G. Schwerdt:—(Mr. Holman): “Now that farms in this district are getting into working order—scrub clearing being almost a thing of the past—more attention can be paid to fallowing. The chief difficulty in laying down any one method is the number of different types of soil found on the average farm in this district. Even in a 150-acre paddock several types of soil will be found, and to get the best results each class of land needs a different working. This cannot be done when the land is so patchy, and all that can be advised is to work on a general scale. The depth of ploughing in light soil being adjusted with the plough lever. Careful treatment of sandy soil is required to prevent drift, but I do not advise leaving sand rises unworked or they may blow out in deep holes and leave them unworkable, but by ploughing the stumps and roots are removed, and then, if they do drift, this will allow them to drift evenly. If sandhills are left in a natural state they become a harbor for vermin and catch all the drift from surrounding land, which tends to make them impassable. I favor the mouldboard plough for fallowing because it leaves the land rougher and helps to hold drift. Fallowing helps to spread the work more evenly over the year, and stumps can be picked and burned or carted off, thus saving time when seeding. Fallowing should start as soon as possible after seeding and before the weeds get too big, then it will not be necessary to work the fallow so much. No mallee farmer should

be without sheep; besides being a very good sideline and providing cheap meat, they assist materially in keeping weeds in check and consolidating the seedbed, and in this district they do the last-mentioned job better than any implement. When fallowing is finished and stumps picked, the fallow should be cross-harrowed and left until late spring rains before working again, sheep being used to keep weeds down." (Mr. Kelly): "Fallowing is now essential in this district. We have old land that is getting grassy and setting firmer, this land needs working. Fallowing consists of three main points—preparation of seedbed, moisture conservation, and weed killing. By preparing the seedbed at fallowing time, the land is in the right condition for the combine at seeding. By conserving moisture, Nature is assisted and soil bacteria encouraged. By killing weeds the fallow is practically free from weeds, so that seeding may be started shortly after the first seeding rains have fallen. Fallowing should be started as soon as possible after seeding. The earlier it is done the better, thus allowing most of the winter rains to fall on the ploughed ground. Ploughing done after the middle of September is of little benefit as fallow. Deep ploughing is not necessary in this district, but it should be deep enough to ensure that all the land is cut, and if possible turned right over, thus making the following working easier. Towards the end of ploughing—if a dry spell sets in—it pays to run over the broken up land with the harrows, crossing where possible. This will check the weeds that have been cut with the plough but have rooted again; and it will also roll the loose stump out on top and make a cleaner job of stump picking. After harrowing, either the combine or cultivator should be used. These implements turn the fine soil on to the firm seedbed and leave the rougher soil and rubbish on top. This checks evaporation and lessens the tendency to drift. Sheep should then be able to control what weeds appear. Next to rain sheep are the best soil consolidators. If summer rains fall, a working with the combine will be beneficial; it conserves the moisture, and when the land is worked damp it reduces the likelihood of drift." (Mr. Schwerdt): "Fallow should be done as early as possible after a good rain has fallen so that as many stumps as possible will be pulled out of the ground. The land should be worked to a depth of about 2in. While fallowing, have the sheep on the paddock to keep the grass short. No fallow should be allowed to become overgrown with rubbish during spring. Cultivators or harrows should be kept at work, or in most cases sheep will do the work required. Fallow should be left rough on account of drift." (Secretary, J. Dyke.)

SIDELINES IN EYRE'S PENINSULA.

[Paper read by Mr. H. Cowley at the August meeting of the Green Patch Branch.]

The relations between lines of main production and side lines has altered considerably during the last few years upon wheat farms throughout the greater part of Eyre Peninsula. Several lines formerly of minor importance have become established as essential or main lines in the business of farming.

In the "Sidelines Competition" conducted by the proprietors of *The Chronicle*, which aroused so much interest on Eyre Peninsula last year, the principal wool-growing breed of sheep—the Merino—was excluded from classification as a sideline. So also were draught horses, although the farmer who keeps a number of brood mares and an entire with a view to raising a few colts and fillies for sale in addition to those required for filling up the gaps in his farm team as they occur, should be entitled to class such activity as a sideline.

Other lines, which on most farms are becoming of too great importance to be reckoned as other than essential or main lines are dairying and poultry keeping. For the purpose of this paper I shall class every activity other than the growing of wheat, and any method of turning wheat to account otherwise than by direct sale, as a sideline.

Our chief concern as we set out to occupy land more suited to the growing of wheat than for any other purpose, is to be wheatfarmers growing the best crops that we are able to produce from our land. After this we are obliged to find what other activities can be successfully carried out in conjunction with wheatgrowing.

Firstly, under conditions such as we have known for several years past, the growing of wheat alone is not a payable proposition.

Secondly, the growing of other crops in rotation and the keeping of some class of livestock are essential factors in maintaining and increasing the wheatgrowing capacity of the land.

Thirdly, whatever the value of wheat may be waste is uneconomic, and in connection with the growing of wheat we must necessarily produce other grain of low market value as well as promoting by soil cultivation the growth of various weeds and grasses which would be of no value unless turned into usefulness through livestock. It is the recognition of and correct balancing of such facts that largely determine the success of farming in a profitable way.

The aim should be to grow the best possible crop and find for it the best available market. The discovery of better ways of dealing with what we have and can produce by the exercise of brain and brawn will also retain for us our title to independence and self-reliance, and to those nobler qualities of manhood which go to make our life and calling really worth while.

The scope for dealing with more wheat by consumption on the farm and offering less of it for direct sale seems at present to be limited by the difficulty of finding profitable markets for secondary products. Consequently our sidelines consist largely of other than wheat-consuming stock.

SHEEP AND WOOL.

Next to wheatgrowing, and in many cases almost equal to it, comes sheep raising, and we have to decide, each one for himself, in what proportion the flock shall stand to cropping. Whether we shall grow less wheat and keep more land open for sheep and, if we do, how far can we go in the direction of leaving greater areas uncultivated without reducing the sheep-carrying capacity per acre? These are questions that have been with us for a number of years, and our answer from time to time has been to a great extent guided by the relative prices of wheat and wool. Then again we have to decide whether we shall aim at keeping sheep for the production of wool and, if so, for what class of wool, or whether for the fat lamb or mutton market, or for a combination of several or all purposes. Consequent upon our choice we must again choose the breed or cross breed suitable for our purpose, and for our country and its conditions. Nor does our scope for choice end here, for the fine art of choosing is in the selection of the individual within the breed bearing the characteristics which make for success in raising a profitable flock. I incline to the belief that in a country suited to the production of high-class wool we shall never be able to afford to sacrifice our opportunities as suppliers of the world's finest wool for a somewhat doubtful position among the meat suppliers for distant lands. When markets are favorable we may, to a limited extent, profitably cross-breed with approved mutton-producing sires upon a portion of our Merino ewe flocks, and possibly to a more limited extent even introduce pure mutton breeds, but we must continue to breed and maintain the wool-producing qualities of our Australian Merino.

ROTATION OF CROPS.

We may regard the growing of oats or barley in rotation with wheat as a sideline, and at this point may connect the growing of oats with the keeping of sheep, for by hand-feeding with this grain when pasture feed is scarce we may carry through a flock of greater numbers than it would otherwise be safe to attempt to keep, and particularly we may assure sustenance for the ewes at lambing time. We may grow oats after wheat only as far as is necessary to keep the land free from "take-all," or we may grow as much oats as possible as a second crop in rotation or even as a third to be able to carry more sheep than the pasture can be expected to feed, and supplement this with oat feeding in self feeders for a long period of the year. We may even consider the growing of oats on a portion of the fallow in lieu of wheat, which is a practice on some farms where large flocks are kept.

Rye, peas, and melons may also be grown as sideline crops for stock feeding purposes as well as various pasture grasses and clovers (where soil and climate are suitable).

DAIRYING.

Of recent years—with low prices ruling for wheat and wool—we have been awakened to the importance of dairying on the farm, and the condition of overseas markets for wool and frozen lambs on the one hand and butter on the other will greatly affect the proportions between sheep-raising and dairying in the near future. Other factors have to be considered, particularly the ability of the farmer and his family to cope with the extra work associated with dairying. So far as feed supply is concerned, it is largely a question as to whether any particular pasture or garnered crop can be best utilised by sheep or cows for what will feed one will generally be found suitable for the other except in cases of sparsely pastured country or areas distant from the homestead which can be turned to most profitable account by sheep.

It is pleasing to observe that with the recent revival of dairying on farms there has come also a more general recognition of the importance of good breeding in dairy cattle, resulting in a marked and fairly rapid improvement in the class of animals kept. We must remember that we are as yet only at the beginning of the process of improving the producing capacity of the farmer's dairy cow, and still have much to learn and plenty of room for the extension of efforts in this direction. As with sheep, so also with cattle, the art of good breeding lies in the selection of the individual. To stop

[illegible]

● FULL MOON.

at the selection of a favored breed and expect the breed to do the rest without further selection can only end in a low producing herd in comparison with what can be accomplished by breeding only from the best and checking results by actual test records.

Improvement must be the constant aim, whatever breed we may favor. The breed itself may be chosen according to circumstances, such as whether we require quantity of milk merely, or as is more generally the case whether quantity of cream is the main consideration, or whether being out of touch with facilities for the convenient disposal of cream, hopes of profit may depend upon the production of dairy butter, the secondary productions from skim milk, and the raising of male cattle for beef.

POULTRY.

Poultry is a line that is destined within the next year or two to become altogether unprofitable from a marketing point of view in the outback areas where eggs cannot be delivered quickly to an export depot at least twice a week on account of the constantly receding value of second-grade eggs. This should not prevent the outback farmer from utilising a few birds bred and fed in such a way as to provide his household with a regular supply of eggs and table poultry, thus turning the consumption of by-products to profitable use.

In contrast to the state of affairs existing outback we have the growing importance of poultry keeping on the farm in the more conveniently situated districts, and we may even consider the advisability of feeding a quantity of wheat to flocks of laying hens as an alternative to direct marketing of the grain. Certainly we have to look overseas for a market for eggs produced in quantity, and consequently home market values are governed by overseas market prices, and just as certainly our market and to some extent our price will be improved by the regularity of supplies and the quality of the product. Hens that lay regularly and lay an exportable egg are our hope in this direction. Wise selection in breeding, coupled with proper feeding—not necessarily more expensive feeding—and cleanliness and promptitude in handling and marketing eggs are among the essentials in the elevation of poultry keeping to the position of a profitable and important sideline. Neglected fowls may easily become merely unprofitable consumers of unmarketable by-products and general farmyard scavengers.

PIGS.

A few pigs on the farm are useful to eat what is not suitable as food for other animals and poultry, and in turn to provide a portion of the meat supply for the household. The raising of pigs for market as a source of profit is a line of activity dependent upon a number of circumstances, the chief of which are:—The state of the market for pig products, and the quantity of available by-products from other lines of farm production which cannot be turned to more profitable account by feeding to other stock. One fact of importance is that pigs can be bred and reared fairly quickly—provided one has some foundation stock—when necessity arises, and can quickly be quitted, though almost invariably at a loss when a quick clear-out is unavoidable. Considering pigs as being secondary to other sidelines we may govern our activities in dealing with them by our answers to a number of questions including:—Can we feed wheat to pigs more profitably than by selling direct or by feeding to poultry? Can barley or peas be grown as a secondary crop and fed to pigs more profitably than to poultry or sheep or than by being sold direct as grain? Can oats or any pasture be turned to profitable account by pigs if not required for cows or sheep? Can skim milk, if produced in quantity be more profitably consumed by pigs than by its use for raising calves or for making up a protein-rich food for poultry, taking the place of more expensive food, such as meat-meal? The answer to these questions must largely be dependent upon the kinds of other stock kept on the farm and the relative numbers of each, having first taken into consideration the market demand for pig products. The foregoing form the principal sidelines from which we may hope to materially increase the income from farming activities by producing in fairly large number or quantity, as the case may be.

Numerous minor lines may be included in the list of activities which—while probably not producing an appreciable quantity of saleable produce—may help to provide an inexpensive living for the farmer's household or to lessen the expense of working, and of the upkeep of the working plant and farm buildings and other improvements. To deal with such as these in this paper would make it rather lengthy for present discussion, and would probably distract due consideration from some of the points already raised in connection with the major sidelines, though we cannot in actual practice afford to dispense with any activity with which we are capable of dealing, however relatively small and unimportant, if it can be applied to make farming operations more effective and—what is not to be overlooked—more interesting to ourselves and families—particularly the families.

HOW TO OBTAIN MAXIMUM PRODUCTIVITY FROM A SWAMP HOLDING.—In the course of an address on this subject, Mr. P. Bailey said the factors governing efficiency in the use of the rich fertile soils of the reclaimed areas could be summed up under the headings of irrigation, drainage, herds, fodders, sidelines. Maximum productivity could only be obtained from cows, although some consideration had been given to the

growing of potatoes, onions, or maize as the principal money products. The lay-out of a block had a large effect as to how economically the block could be managed. Irrigation lay-out was very important, and paddocks must be so placed that the stock had easy access. Where pasture was grown the paddocks must be suitable to allow for a certain period of rotation, both in grazing and irrigation. Owing to the many different shapes and gradings one could not define any definite lay-out. However, one could realise how much easier the work could be carried out if a block was well laid out for accessibility. Efficient irrigation and drainage governed the success of production, although at the same time something efficient to turn the production into a saleable article was also necessary. On and off with the water as quickly as possible was a motto which should always be practised when irrigating. Channels must be clear, with good access to the drainage channel, which in turn should be large enough to get the water to the pump quickly. A most important point was efficient pumping to maintain a 27-inch water table. There were many varieties of fodders suitable for irrigation conditions. A perennial fodder saved the expense of seasonal cultivation, which left a space of non-production every time it was re-sown, while the perennial type would last quite a long period without re-sowing. Of the perennial fodders two species existed under local conditions. Lucerne was used mainly as a crop to mow for hand feeding. The perennial pasture was most satisfactory to graze. The care and management of the above types were worth consideration, as the continuance and height of production solely depended on efficient management. Lucerne, if cared for would give good results for 14 years or more. The rotation system of cutting and watering this fodder must be observed with much care. In the summer months a rotation of six weeks could be maintained for cutting, and as the weather cooled off and shorter days set in the period of rotation must be lengthened. The care in irrigation of lucerne was very important, and a good stand could be ruined in a few hours. Lucerne planted on the heavier types of swamp soil, which were generally the hardest to drain—other factors being equal—should be watered about every 6 weeks, and on the lighter soils, near to drainage, every 3 weeks would give more production. The maintenance of the stand would be greatly increased if items such as watering, cutting, avoidance of any unnecessary traffic, especially in frosty weather, were always kept in mind. The permanent pasture needed just as much—or, perhaps more—attention than lucerne. Pastures had some very peculiar habits, and must be studied from the day they were established. Presuming a perennial certified pasture of the correct type for swamp conditions:—To obtain the most efficient results, it should be fenced into small areas, so that it could be grazed on a definite rotation, and watered with ease, with convenient access to each block. The rotation of the pasture paddocks was very important, and must be watched from day to day, as it had an important effect on the composition and growth of the swath. It was not wise to graze very heavily—just enough not to damage the crown of the plants. Three to four days in a paddock was plenty. For cows, a 24 days' rotation, varied a little in the winter months, seemed to work very well. During the heavy spring growth the pasture was inclined "to get away." This was the time for the mower to get to work, and ensilage could be made from the surplus, so that when winter set in the surplus could be fed to maintain a higher percentage of stock over the year. If this heavy flush of foliage was not conserved, most of it would be wasted, the plant injured, and the carrying capacity not fully utilised. The lecturer illustrated the seasonal growth of perennial pastures with graphs prepared at Wood's Point. The only animal suitable for turning the fodder into saleable product was the cow. Unless the cow had the qualities of a good producer the highest possible return from the block could not be obtained. The cow was the "factory," and she must be in good working order. Aim at improving her, and gradually build up a higher yield per acre per annum. Unfortunately producers were going through a period of very low prices, and it was hard to make the cow pay its way. With low prices, it was most necessary to increase the herd's production. Every extra gallon reduced costs per acre. The inclination for any sideline depended on the person, and his preferences. Poultry, pigs, potato and onion growing, if they could be managed, would all help to balance the budget. The type of machine used for working the land, harvesting the feed, or milking the cows greatly added to the efficiency of a well-worked block, and also lowered the cost of production to a large extent, if used in the correct way. A machine in bad order became very costly, and it was often that a little repair at the correct time would save much in the long run. (Secretary, F. Barr.)

PARRAKIE (Average annual rainfall, 14.49in.).

August 8th.—Attendance, 12.

QUESTION BOX.—The following questions were submitted for discussion:—What is the best method of getting water from a bore at the foot of a rise to the top, situated 100 yards distant? Answer—Mr. Beelitz advised the use of a stuffing box, by which

means the water could be forced to any position desired. Share plough v. disc? Members favored the share plough where it was possible to use it. Is deep fallowing of any benefit in this district? Opinions of members were divided. Mr. A. Beejitz favored deep fallowing on heavy land, and shallow working on sandy land. What is the cause of so many stock dying between seeding and harvesting? It was thought that horses were allowed to graze too long on the stubbles and became sanded, whilst insufficient minerals in feed for cattle caused them to chew bones, and so contract disease. What is the best way of getting rid of weevil in a wheat stack? Answer—Mr. F. Gravestocks advised the use of copper carbonate to dust the shed after the wheat had been removed. Mr. Irrgang had used formalin with good results. What is the best time for shearing in this district? Answer—Mr. Beelitz said that the time of shearing should be governed by the intentions of the farmer. For instance, if he wished to fatten wethers it would be wise to shear as early as possible. On the other hand, later shearing was usually favored with better wethers. Hoe *versus* disc drill? All members favored the hoe, but considered that for this district the combine had definitely displaced the former types of drill. The best methods to white metal bearings, plough boxes, &c.? Answer—Mr. Gravestocks said he had metallised some plough boxes about 4 years ago, and found it very satisfactory. He advised that the axle and wheel be removed from the plough and the outer end of the box sealed with plaster of paris. With this there was less chance of the metal spitting, as it would do if wet clay was used. Mr. Cabot said that it was best to wrap two thicknesses of brown paper around spindles when metallising straight bearings. (Secretary, A. Afford.)

WOMEN'S BRANCHES.

BALUMBAH.

July 5th.—Attendance, 17.

ART NEEDLEWORK.—Miss O. Deer presented the following paper:—"Needlework has a distinct advantage over other crafts, for it does not require a special workroom and is a wonderful pastime. Fancywork is very expensive worked, but traced goods can be bought quite reasonably, and worked at a small cost, and so beautify the home. No excuse can be offered for not being able to work the different stitches; there are many useful books which can be bought at a low cost. The 'Melba' art needlework book is very useful; it contains a variety of stitches and crochet edges. The Semco books are also very good. The first thing to be remembered in working is that knots must not be tied. Take a few small stitches on the back to make the threads secure. To finish off, run a few stitches back into the other and be sure to cut the cotton close to the work. It is important to keep the back of the work as tidy as possible; threads should not be carried from one flower to another, because the threads may get caught and broken in the iron when pressing, leaving ends, thus making the work very unsightly. Shading is largely used in working flowers. The outer edge of a flower is darker than the centre, therefore three shades of cotton should be used to tone down the color. Stranded cottons are best for working; one or two threads can be used, according to the stitch used. Indian filling is much better worked with one strand. If two strands are used it has a coarse, heavy appearance, while satin and buttonhole stitch are better worked with two strands. A basket of sweet peas on a cloth or cushion is a very pretty design. Flowers worked in their natural colors look very natural. Sweet peas are very dainty worked in Indian filling; it makes them stand out. The simplest stitches in needlework are stem and back stitch, snail trail, satin, and lazy daisy. Lazy daisy is a stitch that does not wear well, and if bullion stitch is used in its place, will wear well and look nicer. Cineraria is a very simple stitch and has a pretty effect. Keep the stitches even. Baby roses are most suitable for baby's clothes; they are easily and quickly made. (Hon. Secretary, Miss V. Wohling.)

McLAREN FLAT.

August 3rd.—Attendance, 23.

IRISH CROCHET LACE.—The following paper was read by Miss F. Bell, who also exhibited some of her work:—"Of the various kinds of hand-made lace Irish crochet is most interesting. This lace did not originate in Ireland, but was introduced from France to help the cottagers during the famine of last century. Nowadays, though considered rather an old-world art, it has a fascination and unusualness which ordinary crochet work does not possess. There are two forms of this work—the fine baby Irish and that composed of heavy, padded motifs. The latter is more difficult, being worked over a card, the tightening or loosening of which shapes the sprig, and for this reason no definite directions can be given for working and joining the pieces, for it is seldom that two workers will make a sprig exactly alike. The best lace is always firmly and evenly worked, the stitches should be uniform and compact, and the padding cord should never show through the work; loose or ragged crochet makes very inferior lace, lacking in crispness and durability. First decide on the size and shape of the article to be worked, then mark the outline on a piece of calico. When padded motifs are worked and drawn into shape, cut the padding cord, leaving about a quarter of an inch, which must be securely sewn down at the back of the work. Tack each piece down firmly, wrong side up, on calico foundation in the position they occupy in the design. Then proceed to work the connecting bars or filling. The advantage of having the wrong side up is that the filling can often be carried across the back of sprigs and continued in another space without breaking the thread. Fastening off can be done more easily and securely. Sometimes joinings and fastenings are done with a sewing needle; this is quite allowable. When lace is complete, cut tacking threads at back of foundation to avoid risk of cutting lace. Baby Irish lace derives its name from the fineness and daintiness of the work. It is usually fairly simple, being composed of medallions made of a tiny motif surrounded by picot filling; these pieces may be round or square. The stitches used in Irish crochet are the same as for ordinary crochet. Regarding materials, any fine hard twisted cotton is suitable, and a heavy broder for padding. A fine smooth hook is necessary for good work. It is important to keep the work fresh and clean, and the final pressing should be done under a piece of damp new calico. While still steaming, iron lace itself until dry. This gives the lace a firmness not obtainable by any other method." (Secretary, Mrs. D. Elliot.)

MINNIPA.

Although there are only a few Women's Branches in the Central portion of Eyre's Peninsula, a Conference was held at Minnipa on October 6th, when there was a good attendance, including a number of ladies residing at Minnipa, where there is at present no Branch of the Bureau. After attending Mr. Anderson's address on "Poultry" a successful meeting took place in an adjoining hall, when Mrs. Ohlman, of Warramboo, read a paper on "Wool and Its Uses," and exhibited several articles made from wool.

MORCHARD (Average annual rainfall, 13.59in.).

July 7th.—Attendance, 11.

THE VEGETABLE GARDEN.—Mrs. W. Twigden read the following paper:—"In every garden there should be a vegetable patch. To make a vegetable garden successful it is most essential that there be unfailing vigilance in the new sowings of quick-maturing crops and subsequent care of the growing plants. A good working rule is to make successional sowings, when the preceding sowing is showing above ground. It is important to sow seeds of turnips early in February. They make a welcome vegetable on the table in late autumn. They are tender and quickly grown. Lack of success is frequently due to late sowing. Successional sowings may be made weekly until the end of March. Red beet is a useful vegetable for salads, but should be grown quickly and pulled when young. Where space can be spared an effort should be made to grow a few rows of silver beet; it is a good vegetable for the hot weather. Do not neglect to raise cabbage and cauliflower plants; they will be ready to plant out early. Put in a few carrot and parsnip seeds. Keep the hoe busy; weeds destroy the young plants."

VEGETABLES: THEIR VALUE AND USES.—Paper read by Mrs. Mills:—"The value of vegetables as an article of diet is well known. Vegetables contain many very valuable mineral salts and vitamins that are most necessary to good health. Cabbage, cauliflower, lettuce, celery, and spinach are very valuable for the mineral salts they contain. There is a time limit for cooking green vegetables, and when that is reached they should be taken up and drained. The tomato is rich in vitamins and can be eaten raw or cooked. Onions, potatoes, parsnips, carrots, turnips, and beetroot are best when cooked fresh and young. Potatoes are the most used vegetable, and are usually served with other vegetables. Care should be taken when boiling them not to use too much water. Water in which vegetables are boiled is very good for soups. The goodness of the potato is next to the skin and they are best boiled in their 'jackets.' Wherever possible, every household should have a vegetable plot." (Secretary, Mrs. Schulz.)

August 4th.—Attendance, 10.

PORK AND ITS USES FOR SMALLGOODS.—Miss B. Halliday contributed the following paper:—"The best months to kill a pig are May, June, July, and August. When a pig is being killed save the blood in a vessel into which has first been placed some salt otherwise it will go thick and curdle. Clean the runners in several changes of cold and hot water and then soak in salt and water all night. Finally run warm water through them before using. Where there is only one pair of hands to do the work, put away the main part of the pig first. Save any small pieces of meat, which can be used for sausages. The following is a recipe for Scotch haggis:—Mince liver, heart, and kidneys, then about 1½ cups of fat cracklings, 2 medium-sized onions, 2 slices of breadcrumbs, then add 1 handful each of flour and flaked oats or oatmeal, ½ to 1 packet mixed spice, according to size of mixture, a little thyme, salt and pepper to taste. Mix well together and fill into the big stomach. Put in a saucepan of boiling water and boil for about 1 hour. It is then ready to cut and fry when cold. Sausages—These are made from scraps of meat cut off hams, &c. Mince it all and add breadcrumbs, thyme, pepper, salt, and onion to taste, and fry for breakfast. If the sausages are to be kept leave out the bread and onion. Mix well and it is then ready to fill into the small runners. Black Pudding.—Cut cheeks off pig's head and cook head and heart and other small pieces. Also cook 3lbs. rice in water and add a little salt. Leave until next day and put through mincer. Add rice, marjoram, blood, salt and pepper to taste, and a little allspice. Mix together and fill into runners; if too stiff add a little hot water. Put sausages into a saucepan of boiling water to simmer for 20 minutes. White Puddings—Boil one pig's liver and fat from the cheeks. When cold, mince and add 2 cups of breadcrumbs. Boil an onion and strain the water into the liver, &c.; add pepper, salt,

and marjoram to taste. Mix all together and fill into runners. Prick before boiling. Boil in large saucepan with lid on for 15 minutes. *Metwurst*—Mince 10lbs. of beef and 20lbs. lean pork, then add 1 teaspoonful each saltpetre and sugar, a small handful peppercorns, 1 nutmeg, pepper and salt to taste. Mix well together; then fill into sheep runners and hang up for 24 hours. Smoke for two or three days." (Secretary, Mrs. C. Schulz.)

PINNAROO (Average annual rainfall, 14.54in.).

July 7th.—Attendance, 19.

PASTRY.—Mrs. Hill read a paper on this subject and displayed articles made from the following recipes:—"*Cornish Rolls and Pasties*—1lb. stewing beef, 2lbs. potatoes, 1lb. onions. For rolls, use a fine mincer, for pasties, the coarser one. Mince meat, onion, and potato, and mix well with salt, pepper, and thyme. When this is well mixed make pastry thus: 1lb. flour, 6ozs. dripping, 2 flat teaspoons cream of tartar, and 1 teaspoon carb. soda. Rub the dripping well into the flour, add the rising. Mix with cold water. For rolls, roll the pastry very thin; for pasties, a good deal thicker. Bake at once. *Flaky Pastry*—Suitable for apple pie and all meat pies, except Cornish pasties— $\frac{1}{2}$ lb. plain flour, $\frac{1}{2}$ teaspoon baking powder, 1 pinch salt, $\frac{1}{2}$ lb. fat, $\frac{1}{2}$ pint water. Method—Sieve flour, baking powder, and salt; divide fat into three parts. Rub one part into flour; mix flour with water into a soft dough. Lift dough on to a floured board, roll out into an oblong shape, spread one-third of the fat on the dough in small pieces, leaving about $\frac{1}{2}$ in. margin all round. Sprinkle lightly with flour and fold into three, turning the top down first. Turn pastry around with the closed side to the left hand. Roll out three times as long as it is wide. Spread another one-third of the fat and flour it. Fold into three and turn closed side to left hand. Roll out again. Fold once without fat and roll out to shape required. Never decorate the edge of flaky pastry, a cut edge rises much better. *Rough Puff Pastry* for tarts, pies, and rolls— $\frac{1}{2}$ lb. flour, $\frac{1}{2}$ teaspoon baking powder, 1 pinch salt, 5ozs. shortening, 1 egg yolk, 1 teaspoon lemon juice, 1 gill water. Method—Sieve flour, baking powder, and salt; add shortening in small pieces, the size of a nut; chop it in with a knife. Beat yolk, water, and lemon juice together. Mix flour with liquid into moist dough, using a knife for mixing. Turn on to floured board and knead lightly. Roll into oblong and put pieces of butter on in lumps. Flour lightly, fold over and roll, or press again, and continue this process until all the butter is used. Then roll out again and it is ready to use. *Puff Pastry* for jam tarts—1lb. flour, 1lb. butter, juice of a lemon, 1 gill of water, 1 pinch salt. Sieve flour and salt, mix water and lemon juice. Mix flour into smooth dough with water. Turn on to floured board. Roll out and put butter on in pieces, dredge lightly with flour, fold over and roll out lightly. The more times this is done the lighter will be the pastry. Use as little flour for rolling as possible, just enough to keep the pastry from sticking to the board. Continue this rolling out process and putting the butter on in lumps until all the butter is absorbed. Then give it an extra fold and roll out to get the butter well mixed in with the pastry. This can be and is better for being kept overnight in a cool place and next day can be rolled out once more and cooked. The lemon juice used in the mixing helps to make pastry digestible. Pastry should be made in a cool place, put on a clean, cold oven slide, and cooked in a hot oven. Sift flour, salt, and baking powder to remove lumps and mix. Rub fat into flour with tips of fingers, raising fingers out of the flour so that air may mix with the flour as it falls. When cutting pastry, make a clean cut, and leave no ragged edges. Use a hot knife. All pastry needs a hot oven. Pastry butter should be at least three days old. For pastry, keep all ingredients as cool as possible, and have a very hot oven to prevent the butter from escaping from the pastry." (Secretary, Mrs. F. Atze.)

RENDELSHAM.

August 2nd.—Attendance, 10.

HOME GARDENING.—Miss P. Foster read the following paper:—"The first thing to be attended to is the cultivation of the surface of the soil, for when warm sunshine follows rain the soil is liable to set hard and crack on the surface. Especially is this the case with heavy soil, but a thorough early working, followed by regular attention to the surface with the hoe, will keep the soil in good condition. Weeds will make great headway if not checked, but the constant use of the hoe will keep them under. Roses are bursting into growth, and soon the garden will be bright with a variation of colours. The enemies of the rose will destroy the season's work, unless immediate

steps are taken to eradicate them. When the first signs of mildew appear, dust the foliage thoroughly with sulphur. This should be done in the morning when the foliage is wet with dew. Aphis is easily checked by spraying with a good strong tobacco mixture. A careful watch should be kept for suckers, and as soon as they appear pull the soil away lightly without disturbing the plant and cut close to the stem. In spring chrysanthemums may be taken from the cutting bed and planted where they are to remain. The soil should be fairly rich, but avoid rank manure; this produces coarse blooms. All lovers of dahlias should make a planting in September to get early blooms, and later on, say in December, make a final planting for autumn display. Good blooms cannot be obtained by planting old clumps as they are taken up; plant a piece with only one or two eyes as shoots on it; these will give much better blooms, and the plants will be more vigorous. If raising from seed, sow in September and plant out seedlings as soon as they are large enough to handle. Cut off all the blooms on early flowering Iceland poppies before they reach full bloom. If they are allowed to seed the plants will rapidly die off. Give poppies an application of liquid manure every week and the flowering will be prolonged. A handful of fine dry grass sprinkled over a bed of seedlings will promote rapid growth. For Iceland poppies and stocks this is particularly beneficial. When setting carnation cuttings bend back the five lowest leaves and bury these with the stem of the slip. Cuttings thus set are practically certain to grow into healthy plants. Powdered charcoal sprinkled round roots of carnations will greatly improve the colours of the blooms. During cold days the growth among vegetables is virtually at a standstill; the wisest course is to keep things going as far as possible by constant use of the hoe. Get as much air and sunshine in the soil as you can, and the result will be better crops and stronger plants. Time should be taken to make preliminary arrangements for next season's vegetables. Get beds or boxes ready for early seedling tomatoes. Do not make the soil over rich—a mixture of leaf-mould and loam is good enough. See that the drainage holes are clear; a stodgy seedbed means sour soil. A sprinkling of wood ashes on the surface after sowing will be beneficial. Plant seeds singly; 2in. each way is sufficient. Any seeds failing to germinate can be replaced. When second leaves appear, remove to another box. This will check leaf growth, and by retarding the flow of sap will make sturdier

THE NEW MODEL DOMO

AWARDED THREE PRIZES AT THE ROYAL SHOW, ADELAIDE, 1932

ARRIVED !!

SKIMMING BOWL, semicyclic.

plants. In open positions broad beans, peas, cabbages, cauliflowers, and Brussels sprouts can be planted out. If using seedlings from an outside source, dip each plant in a solution made of 1 gallon water and 1 teaspoon of nicotine sulphate. This bath will eliminate aphids and green fly and give the plants a good start." (Secretary, Mrs. C. Andrews.)

TANTANOOLA.

August 2nd.—Attendance, 13.

CAKE RECIPES.—Mrs. M. Telfer supplied the following:—“*Bakette Ruffs*—One egg, $\frac{1}{2}$ cup each sugar, butter, chopped walnuts, and cocoanut, 5 cups Bakettes. Cream butter and sugar, add egg, and beat well, add walnuts, cocoanut, and Bakettes, mix lightly. Put 1 dessertspoon in paper patty and bake in very slow oven 20 minutes. Leave in pans until quite cold. Mixture is dry to crumbly before cooked. *Slugs*— $\frac{1}{2}$ lb. butter, $\frac{1}{2}$ lb. sugar, 1 egg, $\frac{1}{2}$ lb. flour, 1 teaspoon cream tartar, $\frac{1}{2}$ teaspoon soda, 2 tablespoons cocoanut. Roll lumps the size of walnuts into long shapes and roll in cocoanut. Bake until a golden brown. *Plain Cake*—One cup cream or $\frac{1}{2}$ cup butter, 1 cup sugar. Beat until sugar dissolves, then add 1 egg and beat again. Then add 3 cups S.R. flour, 1 cup milk, and a little essence. Bake in a moderate oven. This mixture can be divided into three parts and colored with cocoa and cochineal to make a ribbon cake. Also use a dessertspoon of cocoa and make a dark cake. It can also be made into lamingtons and date cake. *Cocoanut Shorts*—One cup S.R. flour, $\frac{1}{2}$ cup sugar, 1 tablespoon butter. Mix together and make a dough with a beaten egg. Roll out to fit a tin, spread with jam, then with the following mixture:—Beat 1 egg with 2 cups sugar, add 1 cup cocoanut; flavor with essence of almonds, spread on jam, and sprinkle with cocoanut on top. Bake until brown. *Rainbow Roll*—Two heaped tablespoons butter, 1 large cup sugar, cream 3 eggs, one at a time, beating well between each one, a pinch of salt. Gradually add $\frac{1}{2}$ cup milk, then sift in 2 cups of flour and 2 teaspoons of baking powder. Mix lightly, then divide in three parts. Color one with cochineal and the other with a dessertspoon of cocoa dissolved in two tablespoons of boiling water and a few drops of vanilla. Cool before adding to mixture. Have nut loaf tins greased ready to put mixture in, one dessertspoonful of each color until all is used; only fill tins half way. Cook three-quarters hour in moderate oven, then roll in pink or brown icing and then in cocoanut. *Cocoafoons*.—Beat 2 egg whites with $\frac{1}{2}$ teaspoon of salt until stiff. Whisk in 1 cup sugar (2 tablespoons at a time), and add slowly 2 cups cornflakes, 1 cup desiccated cocoanut, and $\frac{1}{2}$ teaspoon flavoring. Drop from a spoon on to a greased slide and bake 10 minutes in a moderate oven.” (Secretary, Mrs. E. Telfer.)

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences.

District Conferences will be held as follows:—

River Murray Swamp Areas, at Murray Bridge, Thursday, February 15th.

Lower North, at Riverton, Thursday, February 22nd.

Yorke Peninsula, at Port Victoria (Wauralte Branch), Wednesday, March 7th.

South-East (Upper), at Wolsely, Wednesday, March 21st.

South-East (Lower), at Tantanoola, Wednesday, April 11th.

Dairying, at Milang, Wednesday, May 9th.

Eyre's Peninsula (West), at Ceduna, Wednesday, July 4th.

Upper North, at Wilmington, Wednesday, July 18th.

In each case the Conference will commence at 10.30 a.m. Members of Branches are invited to submit papers and questions for the agenda.

Frost Prevention.

An illustrated article by Mr. J. B. Harris (District Horticultural Instructor) on Frost Prevention by Orchard Heater, and embodying the work of the Committee in the Light's Pass district, will appear in the January issue.

Seed Wheat from Turretfield.

Limited quantities of seed wheat will be available from Turretfield this season.

The varieties offering consist of NABAWA, WARATAH, SULTAN, FEDERATION, GALLIPOLI, SWORD, and RANEE.

The price for graded seed has been fixed at 3s. 4d. per bushel on trucks Sandy Creek, and as the amount of each variety available is relatively small, prospective purchasers should lodge their orders at an early date. All inquiries for seed wheat should be forwarded to the *Manager, Turretfield Seed Wheat Farm, Rosedale*.

Argentine Wheat Crop: Locusts.

In his report for September the Argentine correspondent of the Empire Marketing Board stated that up to the end of that month 3,635,173 tons of wheat had been exported, leaving a balance of 481,379 tons still available for export. Outside of "orders" the principal destinations were Brazil, Europe, and the United Kingdom, the largest quantity being shipped to Brazil. Argentine has not been affected by the limitation of wheat exports, and it is felt that as the 7,000,000 tons allotted to the Republic for two years are more or less what would normally be her exportable surplus, there will be no great difficulty in keeping within the limit set. In the greater part of the wheat zone the reports indicate that there has been a wonderful response to changed weather conditions. Most of the fields are looking fine, and their condition is probably fully up to the average for this period of the year.

In August locusts were reported as being present in unusual numbers—even greater than last year, which was the worst for very many seasons. They usually reach the damaging stage about November, when the next crop of insects is in the hopper stage of development. In preparation for the coming fight, the National Government had voted a large sum of money, part of which had been spent in supplies of galvanised sheets used in the erection of barriers for trapping the insects. Past experience does not encourage the hope that these measures will be more than partly successful, and unless Nature takes a hand, there is very likely to be some damage. The extent of the damage will depend largely upon the stage of development of the plants when the insect gets busy. If the wheat is well advanced and approaching ripeness, they will turn to something more palatable if it is available.

THE GREAT AUSTRALIAN TYRE—AS BRITISH AS THE EMPIRE

A SHOCK ABSORBER INSIDE A TRUCK TYRE?

Yes—A CUSHION UNDER-TREAD
THAT STOPS ROAD SHOCKS
AND PROTECTS THE CASING . .

The Dunlop "Gold Seal" Truck Tyre has an exclusive Cushion Under-tread that wraps right around the casing under the tread and side walls. This "shock absorber" prevents the smashing blows of the road from damaging the casing—and is also a non-conductor of heat. The Dunlop Cushion Under-tread prolongs the life of the tyre and practically eliminates all danger of blow-outs.

Ask your local tyre dealer to show you this sensational Dunlop tyre, and quote you prices. Ask him to explain the double bead wires—each set separately anchored in casing—that are another of the features that make Dunlop "Gold Seal" a stronger, safer and longer lasting truck tyre.

Close-Mating in Pigs.

A farmer purchases a pedigreed "in pig" sow; from the progeny he wishes to retain some of the best sows for breeding, and a boar. What would be the correct procedure in mating; would it be detrimental to future progeny if the boar was put to mother or any of the sisters of the litter? Replying to this question, Mr. W. J. Spafford (Deputy Director of Agriculture) says of farm livestock pigs show all effects from close breeding to a greater extent than do any of the other animals, and in-breeding as suggested is never practised with them. When closely related pigs are mated together the result is usually most unsatisfactory, for although large litters may be secured, the number reared is generally small, and the development of the youngsters very irregular. Frequently, whole litters are useless for any purpose, and in all cases it should be expected that some of the youngsters cannot be reared into normal animals. To save expense and to keep the herd vigorous, the best procedure would be to retain some of the youngsters from the pedigreed sow—if they are good enough to be worth keeping—and make an exchange with a young boar from the litter with one reared by someone in the neighborhood who is breeding the same kind of pigs.

Establishing Lucerne in the Bute District.

During a discussion at Bute on the control of eelworms it was suggested that lucerne might be of economic utility, in so far as it would give a permanent pasture on the lighter types of land which were the most seriously attacked by that pest. Further, if this plant was established, it would give an added advantage by assisting to control the drift to which these soils were liable. Some doubt was raised, however, as to the suitability of the rainfall for a satisfactory growth of the plant. Mr. W. C. Johnston (Agricultural Instructor) states that a striking answer to this question may be seen on the farm of Mr. D. P. McDonald, where an extensive area has been sown to lucerne.

The farm is situated on the western side of the Hummocks Range, about six miles in a south-easterly direction from Bute, and enjoys a rainfall of approximately 16in. per annum. The land is a mixture of types, from the lighter sands, highly liable to drift, to the heavier greyish loams, so eminently suitable for the production of wheat, while throughout the soil is an abundance of nodular limestone, so characteristic of many of our South Australian mallee soils.

The cultivation of lucerne on this farm is a recent undertaking, and it is a pioneering advance in the agricultural practice of the district. It is also one which is likely to enjoy much popularity in the event of wheat prices remaining at the present low level.

Asked as to the history of the venture, the owner explained that he had for many years entertained an idea that lucerne would do well on his land, but that he had been deterred from experimenting by the high price of the seed a few seasons ago. The outlay at that time was so great that it made a trial of the crop an expensive proposition, but when the price fell to the level of last season, it was considered a reasonable gamble. A sack of the seed was therefore obtained during the autumn of 1931 and was sown with the cereal crops during the ordinary seeding operations with satisfactory results.

The plant has established itself on all classes of soil in the field, but there was a definite indication that more stools were to be found on the lighter sandy land; in fact, on two sandhills there was a crop of lucerne that would cut approximately 30cwt. of pure lucerne hay, and it was observed that where cereals had been sown on the stubble the lucerne had completely choked them.

It is of interest to note that the land where the heaviest growth of lucerne is to be seen is of such a sandy nature that the production of cereals on it is a precarious undertaking as the soil is very liable to drift badly. Since the establishment of the lucerne it is expected that this disadvantage of the soil moving will be overcome.

Possibly one of the most remarkable features in the undertaking is the thickness of the stand when it is remembered that it was obtained from a seeding of approximately 11b. of seed per acre. It is evident that practically every seed must have germinated and established itself.

The success achieved in this instance with lucerne is of such magnitude that it gives every confidence in assuming that an equal stand of the crop may be expected on any land of a similar character, and in like climatic conditions. If it is so, then there are considerable areas of land along the Hummocks that it is reasonable to expect will grow lucerne to the same degree of perfection.

In the event of the result of this experiment becoming a widespread activity, it is beset with enormous possibilities, by no means the least of which will be the diversifying of the agriculture of the area. It will become a district in which the production of wheat will play an ever lessening part, while the development of animals for their products, an activity which is not very active at the present time, will become of much more importance. With this greater animal production will come the necessity for a rotation of crops, in which the growing of a leguminous crop will be of great moment and which will be an important advancement in the agriculture of the district, and one that will lead to a general improvement of the soils.

Inspection of Crops.

Early in October Mr. W. C. Johnston (Agricultural Instructor) visited areas in the hundreds of Wokurna and Wiltunga, where it was estimated that 75 per cent. of the crops sown in sand had become a total failure. Some 20 to 30 crops, all with the same symptoms, were inspected and the conclusion arrived at was that the trouble was due to a number of agricultural disabilities, culminating in a very heavy infestation of eelworms.

The land in these hundreds is generally of a poor agricultural type, being chiefly a light reddish sand, liable to excessive drift in seasons of low rainfall and high winds. The exception to this general rule is found in the flats between the hills, where there is a good type of loam. On these flats no difficulty is experienced in the growing of splendid crops of wheat, but for the last three or four seasons the sandy rises have been almost a total failure.

There was evidence that the failure of the crops was not due to the inefficient preparation of the land or to poor farming methods, as may easily be supposed, but that it was chiefly brought about through the land being overcropped with cereals. While overcropping is undoubtedly indicative of poor farming practice, it cannot be altogether maintained as such in a district such as this, where during the past decade, at any rate, farmers have cropped every available acre with exportable cereals in the hope of being able to liquidate their financial obligations.

Added to the effects of the too frequent cereal cropping are the disastrous results produced by excessive drift experienced during the 1927-1930 period. In this drift all the finer, richer particles of soil and humus were removed by the wind, leaving behind only the coarser and much poorer elements of the soil. In many places all the soil was blown away, leaving only the subsoil. In either case the soil is in a poor state of fertility, and it is unreasonable to expect it to produce satisfactory wheat crops.

It is the general experience that wheat germinates readily and makes satisfactory growth while it can draw on the plant food stored in the grain, but that as soon as it becomes dependent upon its roots to maintain it there is a loss of vitality, and it frequently dies. A superficial examination would suggest that the trouble was due to the attack of fungus or eelworms, but it is believed that these parasites are in reality secondary in their attack. Support for this argument can be found in the fact that outwardly healthy and excellently grown plants are often very heavily infested with eelworms.

The solution of the trouble lies in a more varied and wider rotation. In fulfilling this any plants that will make a satisfactory growth should be tried. It would appear that such crops as barley, rye, lucerne, peas, and the encouragement of clover are well worthy of a trial. It is understood that the chief hope of financial returns will be through the medium of livestock, and they will gradually build up the humus content in the soil.

Agricultural Implements.

In a broadcast talk last month, Mr. W. J. Barker, member of the Chamber of Manufactures, mentioned the names of Ridley, Bagshaw, Shearer, Smith, and Illman, who have been instrumental in producing "better farm implements." After referring to the stripper of John Ridley as a most unique invention which, with very slight modifications, remained the best harvesting machine for Australian conditions for a period of 40 years, Mr. Barker stated that the next most notable South Australian implement was the stump-jump plough. So far as he could learn the first stump-jump mouldboard plough appeared in the seventies and the names best known in this connection were J. L. Mellor and H. B. Smith. It was reported that Mr. Smith built the first stump-jump plough at Booleroo Centre in 1876 and that a man named Braybrook worked there and later went to Victoria to commence making ploughs at Braybrook. The name of Anderson was also mentioned in this connection. The manufacture of stump-jump tine cultivators and harrows followed, but no names were mentioned as inventors; these implements originated partly in South Australia and partly in the Wimmera (Victoria). Later the combine was invented in this State, and the foremost machine of its kind for separating wheat from cocky chaff and producing a clean sample was the winnower invented by Mr. Illman, of Dowlingville.

Dairy Certificates.

The following candidates have been successful in obtaining certificates under the Dairy Industry Act, 1928:—

Milk and Cream Testing.—John Thomson, David J. Bennett, Kathleen M. Beauchamp, Laurie J. Allison, Joyce M. Johnston, James F. Ayres, George V. Thiele, Walter L. B. Bell, Gwendoline Coblin, Ludwig M. Hansen, Leslie M. Carlyle, Samuel P. Burton, Gwendolyn L. Blair.

Cream Grading.—Daisy E. Aslin, Tennyson G. Clark, Laurie R. Curnow, Samuel P. Burton, Vincent H. Keenihan, Cecil Howard.

Horse Radish.

The Chief Horticultural Instructor (Mr. G. Quinn) advises the Secretary of the Hope Forest Branch of the Agricultural Bureau, who asked for information how to grow horse radish, that the usual practice is to plant roots procurable from nurseries and seedsmen.

The plant thrives best in very deep moist soil, deeply dug and enriched by rotted animal manure.

The roots are set about 12in. apart in rows laid out 2ft. from each other. It should be noted that the roots possess one or more buds or eyes near the crown, otherwise they may not sprout. The soil is not consolidated by pressure or treading in any way after planting. The autumn or late winter are suitable times for planting the roots. The tops die down in autumn, and the dried leaves may be removed before hoeing up the ground and applying manurial dressings to the land.

The seeds may be procurable, but raising the plants in this way means a delay of one or more years.

Where this vegetable is grown on commercial lines in Europe, two or three beds are grown so that the roots may be dug up for use over a succession of years, as the plants develop to saleable proportions.

VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers, Stock and Brands Department.]

Morgan reports aged mare with severe attack of mange.

Reply—Clip the affected area. Wash with warm water and soap to remove all grease, dirt, &c. Dry. Apply the following dressing:—Powdered sulphur, 5ozs.; olive oil, 1 pint. Shake thoroughly before applying. Give the mare good nourishing feed—crushed oats, bran, and good quality chaff.

Rendelsham asks treatment for worms in pigs.

Reply—A suitable treatment for these parasites is to give once daily for 3 successive days 1 teaspoonful of turpentine per 100lbs. live weight of pig. The day after administering the last dose of turps. give a purgative dose of 2-3ozs. magnos-sulph. (Epsom salts). To prevent reinfestation, the floors of the sties should be thoroughly cleaned once a week and feed troughs and drinking vessels scoured with boiling water also once a week.

Hallett has foal that knuckles over on the front feet.

Reply—As the foal gets older and stronger, recovery without assistance may occur, but assistance may be given by the application of splints made of strong hoop iron. *To Use.*—The legs from knee to hoof should be well padded with cotton wool and the splints applied in the following way:—A length of hoop iron sufficient to reach from below the front of the knee, down front of shank, under hoof and run up to behind the knee at the back should be cut off, well padded with cotton wool, and bandaged to keep wool in position. Put the covered splints into position and apply a firm bandage from knee to hoof to keep it there.

Bunora asks—(1) cause of blood in milk of cow, and (2) how to remove warts from teat of a cow.

Replies—*Re 1:* The occurrence of blood in the milk is due to the rupture of a small blood vessel in the interior of the quarter or the teat, occasioned either through injury—such as bruising—or at times to infection of the quarter with a mild chronic mammitis. In order to allow the ruptured vessel to heal up, the affected quarter should be milked out as gently as possible for a few days, and if it is found that “stripping” causes the bleeding to recur, this part of the milking process should be, for the time being discontinued. *Re 2:* If the warts are pedunculated (i.e., have prominent necks), they can be cut off close to the base with a sharp pair of scissors, and then the stump touched lightly with a stick of caustic. When the warts are broad and flat, they may be treated as follows:—First of all, scrub well with warm solution of washing soda, to which has been added a little lysol; then when all surface scale and debris have been thus removed, exposing the soft surface of the warts, paint daily for a few days with a solution of $\frac{1}{2}$ dram bluestone (copper sulphate) dissolved in 2 tablespoons of water. Paint this on to the warts only, with a small camel-hair brush. Another treatment which is often successful in removing warts, is to wipe the affected parts clean after each milking, and rub in a little castor oil.

FRIENDLY SERVICE ALL THE TIME.

Some of the time, if not all the time, you must save money, but if you are Mr. Average Citizen you know that ALL the time is nearer the mark.

Whatever your margin on any one week's salary, it won't provide for a sudden necessity to pay, say, £50 or £100. No one week's salary will provide education for your children, heavy medical expenses, or comfort in your declining years.

Therefore, to make provision for the big calls, you HAVE to save, more or less, ALL the time. The Commonwealth Savings Bank provides a friendly efficient savings service—ALL the time.

Commonwealth Savings Bank of Australia

DAIRY INDUSTRY PRICES.

ROYAL COMMISSION REPORT TO HIS EXCELLENCY THE GOVERNOR.

[A Royal Commission, consisting of Messrs. W. J. Dawkins (Chairman), Professor A. J. Perkins, and J. W. Wainwright, was appointed in January to inquire into and report upon the disparity between the prices paid by the consumer for dairy produce, the London parities of dairy produce, and the prices received by dairymen for milk and cream, the cause of such disparities, and the remedies therefor. The report is dated October 20th, 1933, and portion of it is quoted below. It is proposed to complete the report in subsequent issues.]

(Continued from Page 435, November issue.)

E. THE CLAIMS OF HOUSEHOLDERS' MILK FOR A HIGHER UNIT PRICE THAN CORRESPONDING MANUFACTURING PARITY.

The claim of the producer of household milk for higher price per unit than that paid for milk required for manufacturing purposes may, of course, be questioned. Nevertheless, it is a claim which is accepted in most countries, although the margin between the two is apt to vary with circumstances. In the main, it is probably based upon the fact that the consumer has always been accustomed to pay a relatively high retail price for his limited daily requirements, and that the producer has always sought to share in the benefits that accrue therefrom. Additional reasons suggested are more costly handling charges and greater care that should attach to the handling of household milk; and, doubtless, these reasons may be accepted when adequate measures of hygiene and sanitation are enforced; but they can hardly be stressed unduly, when the milk of dairy farmers is purchased in bulk by large manufacturing and distributing agencies under contract, on the understanding that portion only of this milk was purchased for household purposes and the balance for manufacturing purposes.

In the 1923-32 period the margin between household milk and manufacturers' milk varied in England from 6d. to 8d. per gallon; in 1933, the former realised 1s. to 1s. 2d. per gallon, and the latter 4½d. only, or a mean margin between the two of 8½d., that is to say, a mean increase of 184 per cent. above manufacturing price.

In South Australia the margin between these two types of milk has never been as great, chiefly because a very large proportion of the milk usually converted into butter in this State can be considered as potential household milk, and has exercised considerable pressure on the metropolitan market. The result of this pressure has been that the wholesale price of household milk has been directly controlled by butterfat prices current at the time and that the margin between the two types of milk has been narrowed down. These facts may be illustrated by the position obtaining in March, 1933, at Murray Bridge, which is both a large manufacturing centre and a centre from which milk is forwarded to the metropolitan area for human consumption. At that time producers were receiving roughly 4d. per gallon for milk for manufacturing purposes, and 6d. per gallon for milk for metropolitan consumption. The margin between the two prices was therefore 2d. only, or an increase of 50 per cent. above corresponding butterfat prices.

Thus it must be admitted that in South Australia the margin between the wholesale price of household milk and corresponding butterfat prices is very narrow; but it cannot be claimed that producers have established a right to a wider margin until such time as it can be shown that household milk is being produced and

handled under conditions that satisfy modern views on hygiene and sanitation. Hence, your Commissioners' recommendations for the control of competition in the milk trade, both within and without the metropolitan area, are made quite as much in the interests of the consumer as those of the producer; and if they are to be given effect to it would be on account of the extra cost of stricter hygienic measures to be enforced upon producers, distributors, and vendors. That the enforcement of such measures will prove of advantage to both producers and consumers, without injuring the interests of legitimate distributors, can best be illustrated from evidence given before the Commission by a large Melbourne distributing firm, probably one of the best firms of its kind in Melbourne.

The firm in question distributes daily about 320galls. of milk, all of which is sold as pasteurised bottled milk. The milk is retailed at 3d. per pint delivered. No bulk milk is retailed by this firm. The usual Melbourne price for the latter was 2½d. per pint delivered in bulk.

The farms supplying this firm's milk are situated at Yarra Glen, about 31 miles from Melbourne. They are under the immediate supervision of the firm's officers and of a veterinary surgeon.

The mean price paid to producers on the farm was at the time 9½d. This price compares very favorably with 8d. per gallon, which was the selling price to vendors of pasteurised milk delivered from the Melbourne Railway Station.

Further, for milk containing more than 4.5 per cent. of butterfat, an additional penny per gallon was paid; another penny per gallon was allowed should the herd be tuberculin tested; and another should the bacterial count of the milk be below 20,000. It follows that farmers delivering high quality milk were receiving for the same 1s. and over per gallon on the farm; and since at the time the price paid for manufacturing milk was no greater than that paid in South Australia, namely, 4d. to 5d. per gallon, it follows that the margin between the two types of milk, namely, 5d. to 7½d. per gallon, was considerably greater than that noted for Murray Bridge.

Eighteen months ago the same firm paid as much as 1s. 6d. per gallon to producers on the farm, at a time when bottled milk was being retailed in Melbourne at 4½d. per pint.

In the opinion of your Commissioners, somewhat similar results, benefiting all concerned, from producer to consumer, are not at all unlikely in our metropolitan area, if wasteful competition be controlled, and sanitary and hygienic regulations be rigorously enforced.

F. TYPES OF MILK FOR HUMAN CONSUMPTION AT PRESENT OFFERING IN THE METROPOLITAN AREA.

Wasteful competition within the metropolitan area is attributable not only to the presence of redundant vendors, but also to an increase in the numbers of metropolitan cows, which in times of economic depression not only demoralises the business of legitimate vendors, but penalises regular country supplies, whose milk can no longer find its usual market. To this extent these surplus cows must be considered as one of the factors tending to lower the wholesale price of household milk, and to prevent its quality from satisfying minimum requirements of hygiene and sanitation.

It is from this particular aspect that it is proposed to examine the various types of milk usually available to metropolitan householders. These types may be classified under the following heads:—

- (i.) Untreated milk, sometimes called warm milk.
- (ii.) Chilled milk that has been brine cooled only.
- (iii.) Bulk pasteurised milk that has subsequently been rapidly chilled.
- (iv.) Bottled pasteurised milk.

(i.) *Untreated Milk*.—Untreated, or warm milk, is milk usually produced within the metropolitan area, but occasionally in immediately adjoining areas. In this connection the cowkeeper is both producer and vendor, since such milk is in the main delivered to consumers by members of his family, or by his employees. Occasionally only is warm milk delivered by free lance vendors, who have no dairies of their own. It is to be observed that, strictly speaking, warm milk is illegal milk, since it is delivered to consumers in contravention of the Metropolitan County Board regulation 36, section 13, to the effect that "Every cowkeeper and dairyman shall properly cool the milk after being drawn from the cow by immediately passing it over a cooler or aerator."

Many of the recently imported but surplus cows of the metropolitan area that contribute to the supply of warm milk, and compete with long-established vendors, are to be found within purely *residential* portions of the metropolitan area. It is recommended that local authorities should be given statutory powers to exclude all cows from well-defined residential areas, a practice which is in keeping with the modern policy of all large centres of population. It has been stated that it would be difficult to find a single cow within eight miles of the Melbourne General Post Office.

(ii.) *Chilled Milk*.—Milk that has been chilled immediately after being drawn can be described as the only milk produced in the metropolitan area, or in adjacent areas, that strictly complies with the regulations under which the Metropolitan County Board inspectors are supposed to function. It can, too, be taken for granted that milk of this type has usually been produced on farms adequately equipped for supplying consumers with a sound commodity. For the most part, this milk, like warm milk, is delivered to consumers by the cowkeeper or his employees.

The experiences of a dairy farmer who has been supplying the metropolitan area with specially chilled milk are given below in illustration of what can be done in this direction.

He is the owner of a herd of 66 milch cows, and delivers once a day in the metropolitan area 100galls. to 120galls. of milk at a temperature of 35° to 40° Fahrenheit.

The new-drawn milk is first allowed to cool down naturally to 65°. During the course of this preliminary cooling the milk is worked over with a perforated plunger—not a good method—in order to assist the escape of gases and remove undesirable odors. Subsequently the milk is said to be brine-cooled down to 30°. The temperature of the milk is never higher than 35° when placed on lorries in the morning for conveyance to the metropolitan area, and never higher than 40° when it reaches its destination. At this stage it is placed in refrigerators, from which it is distributed to consumers according to requirements. These low temperatures keep in check bacterial development and insure to the milk excellent keeping qualities.

At the time the evidence was given this dairyman was realising for his milk 10d. per gallon, delivered at Goodwood.

(iii.) *Bulk Pasteurised Milk*.—Pasteurised milk is milk which has been raised for a specific time to a temperature sufficient to destroy all non-spore producing pathogenic organisms that might be present, and subsequently shock-cooled to temperatures not exceeding 40 degrees. The great bulk of this milk comes from the country; it may be pasteurised at local depots or forwarded to metropolitan distributing depots, from whence it is delivered to vendors or to consumers. Occasionally milk produced within the metropolitan area may be treated similarly.

It is through these large quantities of milk which reach the city in this fashion that pressure is brought to bear upon the price of Adelaide household milk. Similarly, the ready availability of pasteurised milk at central depots has rendered possible the operations of free-lance vendors, who call at these depots for daily

supplies, and who need have no dairy premises or appliances of their own beyond a cart or bicycle and milk cans. They are even relieved of the task of cleaning their cans, which probably is a public advantage. Hence, within recent years the abundance of country pasteurised milk has been an important factor in assisting to swell the number of itinerant milk vendors.

Mr. Rutledge, Senior Dairy Instructor in Victoria, stated in the course of his evidence that in Victoria, no matter what the source of the milk supply might be, no vendor was allowed to operate within the metropolitan area unless he could comply with the department's minimum requirements in the matter of premises and equipment. The view is held there that adequate supervision is impossible without some such provision.

It is obvious that the adoption of the Victorian policy in this matter for the Adelaide metropolitan area would have the effect of reducing the number of vendors, and your Commissioners recommend its adoption accordingly.

(iv.) *Bottled Pasteurised Milk*.—The practice of delivering milk in sealed glass containers is of comparatively modern origin. Nevertheless, it is already in almost universal use in the larger cities of the United States, whilst in London it has captured 50 per cent. of the milk trade. It has become very popular in Melbourne, but in Adelaide has as yet made but slow progress. It has already been indicated earlier in this report that in the opinion of the Commission the use of bottled pasteurised milk should be rendered obligatory by statute for ordinary shop trade.

There is no question that from the standpoint of daily supplies, milk of good quality that is pasteurised and bottled is much superior to the average bulk milk that is hurriedly ladled out at the householder's back door, and which unavoidably comes in contact with unclean hands. From the vendor's standpoint, on the other hand, it presents the advantage of expediting delivery, and of doing away with losses on delivery, which by one witness were estimated at 1gal. in 30galls., and occasionally more.

In this connection it is very necessary to stress the fact that whilst bottled pasteurised milk, if efficiently prepared, can be admitted to offer complete immunity against pathogenic organisms, and high keeping qualities in the milk, these advantages cannot be expected to hold good unless the milk has been handled and treated at centres adequately equipped for the purpose. And, unfortunately, there is evidence in plenty to show if not yet in this State, then elsewhere, that milk is frequently bottled by incompetent hands, or by means of defective plant, or in unsuitable surroundings. It has indeed been stated that milk has been known to have been bottled from the tail of the milkman's conveyance in the course of the early morning delivery. In the circumstances, and since the householder's suspicions will have been lulled to sleep by the bottle, and since the usual precaution of scalding prior to use will be deemed quite superfluous, inefficiently or carelessly bottled milk is potentially more dangerous to the consumer than the customary milk ladled out at his back door, against which experience has more or less adequately armed him. Hence, since the progressive increase in the use of efficiently bottled milk is desirable, and its exclusive use in shops is deemed advisable, your Commissioners urge that no individual or firm should be allowed to bottle milk for sale except under special licence. They also urge that special regulations should be drawn up defining in detail the conditions under which bottling milk for sale will be permitted, and that licences shall not be issued to individuals or firms whom the licensing authority had reason to believe would be unwilling or unable to comply with its requirements. Breaches of the regulations in this direction should be followed by immediate cancellation of the licence.

From the moment milk enters the "holding" pasteuriser to the moment it is hermetically sealed in a glass container no human contact should be allowed. In other words, all necessary operations should be carried out mechanically under conditions of scrupulous cleanliness and in a still atmosphere, free from dust or

flies. With a view to preventing the bottling of stale milk it is recommended that a minimum bacterial count should be specified. Bottled milk should be maintained at temperatures below 40 degrees from the bottling to actual delivery to the consumer. Each bottle should bear the registered brand of the licensee and the date of bottling should be clearly indicated in ink on the capsule.

It is reported from Victoria that loss of bottles by legitimate bottlers is very considerable; not so much from breakages, but in the main from the actions of unscrupulous persons who do not hesitate to collect them for their own milk, which, presumably, would find a more ready sale under the brand of the rightful owner of the bottle. In this connection your Commissioners recommend that for the protection of both consumers and licensed bottlers the misuse of branded bottles should receive special legislative attention.

It is obvious that the practice of bottling milk and delivering it in an hermetically sealed container represents added service costs which might legitimately be recovered by an increased price to the consumer. Nevertheless, in the United States and in London, no more is charged to consumers for delivered bottled milk than for delivered pasteurised bulk milk. Possibly the more expeditious delivery of bottled milk and the saving of milk wasted in the delivery of bulk milk may be accepted as an adequate equivalent to added service costs. In Melbourne the difference in price is usually $\frac{1}{2}$ d. per pint.

G. CONTROL OF PRICES.

It has already been shown that various factors have of recent years led to chaotic conditions in the supply and delivery of milk within the Metropolitan County District. In the main these factors may be summarised as follows:—

(1) Abnormally low butterfat prices which have led to intense pressure on the metropolitan market by large quantities of surplus country milk seeking an outlet at almost any price.

(2) The tendency of those out of employment, or whose previous occupation was no longer profitable, to claim a share in delivering and distributing milk within the metropolitan area. This tendency has found encouragement in the presence of large quantities of available milk at metropolitan pasteurising depots.

(3) The increased number of licences to vendors and shops.

(4) The inability or unwillingness of the authorities concerned to enforce adequate hygienic and sanitary measures upon cowkeepers and dairymen.

Measures have already been indicated by means of which the number of city vendors should eventually be reduced to normal limits. There remains yet to be considered in what manner the pressure of surplus country milk can best be relieved, and by what measures an adequate price can be secured for producers without unduly penalising consumers.

1. *Control of Supply of Country Milk on Metropolitan Market.*—It has already been shown that in the past, and particularly so in the immediate past, the wholesale price of metropolitan household milk has been dominated by readily accessible supplies of country milk usually sold at butterfat prices; that the presence in the metropolitan area of large pasteurising plants has hitherto served to intensify this position, and that under its influence the margin between the wholesale price of household milk and that of milk sold on a butterfat basis has been reduced to approximately 2d. per gallon only. It has also been shown that this low price—recently 6d. to 8d. per gallon—is not in the best interests of producers, vendors, or consumers.

After very careful consideration of these and other facts, your Commissioners submit the recommendations that follow, in the belief that their acceptance and effective application should ultimately lead to more satisfactory conditions in the milk supply of the metropolitan area:—

(i.) That the sources of supply of all the milk in the metropolitan area shall be under the jurisdiction of one controlling authority.

(ii.) That towards such an end all dairy farms supplying milk for metropolitan consumption, whether situated in the Metropolitan County District or in the country, shall be specially licensed for that purpose by that controlling authority.

(iii.) That such licence, in accordance with existing practice, shall show, among other things, the name and situation of the farm concerned, the names and addresses of the licensee, and the maximum number of cows the owner is authorised to carry under such licence: Provided that such maxima on licensed farms may be varied on yearly renewal of the licence at the request of the licensee and with the consent of the controlling authority.

(iv.) That milk from licensed country dairy farms, for human consumption in metropolitan areas, shall be adequately cooled immediately after being drawn from the cows, and shall not reach pasteurising depots at temperatures in excess of a minimum to be prescribed: Provided that such milk may be sold as untreated milk, if it reach its metropolitan destination at temperatures not higher than 40 degrees F., be immediately placed in refrigerators, and kept there until required for distribution.

(v.) That all pasteurising depots handling household milk for distribution by their own employees or through the medium of vendors shall be specially licensed for that purpose, and shall receive such milk from licensed dairy farms only; that such depots shall keep such records as the controlling authority may prescribe, and that their books and premises shall at all times be open to inspection by the controlling authority's officers.

(vi.) That with a view to spreading the advantages of the metropolitan price for milk over as wide a field as is economically possible, and at the same time providing ample means for meeting metropolitan requirements in months of low production, the quantities of milk sold by licensed country producers to pasteurising depots for human consumption shall in each case be limited to a fixed weekly quantity to be indicated upon the licence certificate of the supplier, and that such quantity shall not be exceeded except with the consent of the controlling authority.

(vii.) That when the recommended authority first takes over the control of the milk supply of the metropolitan area it shall take early steps to ascertain the names of all cowkeepers who, in the 12 months immediately preceding the publication of this report have been supplying the area with milk, and of the weekly quantities of milk supplied by each cowkeeper. The authority shall register the names of all such cowkeepers, and if so desired shall issue to them a temporary permit to continue the supply of corresponding quantities of milk for a period of six consecutive months. And all such cowkeepers shall pay to the authority the value of one-half of the prescribed licence fees. At the end of these six months all those cowkeepers able to comply with the requirements of the authority shall be definitely licensed as metropolitan suppliers, whereas those unable to do so will be refused a licence, unless good cause can be shown that they will be able to comply with the requirements within not more than three months.

(viii.) That the purchasing pasteurising depot shall pay for the household quota of milk of each supplier at the metropolitan price prescribed by the controlling authority.

(ix.) That during a reasonable period pasteurising depots shall not sell or distribute for human consumption more than the sum total of household milk received and purchased by them from licensed producers during the course of that period; and that adequate penalties shall be prescribed for any infringement of this regulation.

(x.) That the matter of supervision of hygiene and sanitation on all licensed dairy farms, wherever situated, in licensed pasteurising depots, on the premises and conveyances of licensed vendors, and in all shops in which milk is sold shall be vested in the controlling authority recommended herein.

2. *Measures of Price Control.*—Whilst it is believed that the suggestion outlined in the immediately preceding paragraphs, together with earlier ones relative to wasteful competition within the metropolitan district should, if adopted, have the effect of very appreciably improving matters for both vendors and consumers, it is certain that producers will benefit little, if anything, from them unless they be associated with some degree of price control. If the principle of price control be adopted, the latter can be made to act effectively at two points only, namely, a minimum price for country cooled milk delivered at metropolitan depots and a maximum price for milk delivered on the consumer's premises; in other words, under such proposals, it would be illegal for a metropolitan depot to pay less than the prescribed price for country milk delivered on its premises for human consumption, or its corresponding country parity, and it would also be illegal for licensed vendors to claim from consumers a price higher than that prescribed by the controlling authority. It is obvious, on the other hand, that neither minima nor maxima prescribed by the controlling authority would necessarily represent the ruling rates of the day; they would do nothing to interfere with the right of wholesale purchasers of country milk to offer prices in excess of the prescribed minimum on grounds of quality, or on any other legitimate trade grounds; nor with the right of retail vendors to charge consumers less than the prescribed maximum on ordinary business grounds. In this connection it can probably be stated in principle that the margin between these two prices—the country producer's minimum and the metropolitan consumer's maximum—should be sufficiently wide to admit of healthy competition among vendors without impairing the average quality of the milk delivered.

It would probably be in the interests of all concerned that the price-fixing powers of the controlling authority should be such as to lead eventually to stability, if not permanency, in the prices paid for milk required for human consumption. Nevertheless, these powers should be sufficiently elastic to render possible occasional variations in prescribed prices, or even temporary suspension of the same, should circumstances render such actions advisable. In any event, although it would be unwise to fetter the controlling authority unduly in this matter, it can be suggested that prices to be prescribed should be made to conform as much as possible to the general economic conditions of the State, from the standpoint of a sufficiently wide cycle of years.

It is obvious that at the outset the prescription of prices can be little more than tentative and temporary in character, nor can finality be anticipated until measures recommended earlier in this report have had time to reduce the metropolitan competition of vendors to healthy limits. Hence, the figures that follow are not suggested for adoption, but are given in order to illustrate the probable consequences of price fixation on the lines indicated above.

Let us suppose that the controlling authority had fixed the minimum price to be paid to country producers at 10d. per gallon delivered in Adelaide, and the maximum price chargeable to metropolitan consumers at 3d. per pint delivered on their premises. In what manner is this regulation of prices likely to work?

In the first place, it is necessary to point out that the maximum and minimum prices, adopted for purposes of illustration, are by no means unreasonable. In this connection it will suffice to recall the case of the Melbourne distributing firm quoted earlier in this report. The daily retail sales of this firm averaged 320 galls. of milk, which were sold at 3d. per pint delivered as bottled pasteurised milk. The whole of this milk was secured from farms within 31 miles of Melbourne, and paid for at the average of 9½d. per gallon on the farms. This price of 9½d. per gallon on the farm can be taken to represent roughly 1s. per gallon on the firm's Melbourne premises. Hence, a minimum of 10d. per gallon at Adelaide wholesalers' premises and a maximum of 3d. per pint to Adelaide consumers can be accepted as figures that do not unduly clash one with the other.

Metropolitan cowkeepers will benefit in some degree from a policy of price control, but their position will be chiefly strengthened by all measures leading to the elimination of redundant vendors, to the limitation of the number of cows in individual herds, and of the pressure of surplus country milk. And the same can be said of a limited number of country cowkeepers, who prefer not to sell their milk through the pasteurising depots.

On the other hand, metropolitan vendors, who do not keep cows, and normally purchase their requirements from pasteurising depots, would probably have to pay proportionately more for their milk than they have recently done.

Licensed country cowkeepers who sold their milk to metropolitan wholesale depots would benefit not only from the control of metropolitan prices, but also from the reduction in the number of metropolitan cowkeepers that would arise from the refusal of some of the latter to comply with the requirements of the controlling authority.

As to consumers, the maximum of 3d. per pint would protect them adequately against attempts at undue exploitation. In addition, they would have the satisfaction of knowing that more rigorous enforcement of hygienic and sanitary precautions would necessarily lead to general improvement in the standard of milk delivered for human consumption. At the time of the preparation of this report, milk was being sold in the metropolitan district at prices varying from 1½d. to 3d. per pint; and it is certain that under a price control policy the lower sweated prices would tend to disappear, with the result that the average price would probably rise; but it is equally certain that normal competition would, except in times of shortage of supplies, tend to prevent the average from reaching the prescribed maximum.

H. QUALITY IN MILK.

The term "quality" when applied to milk infers complexities that are more numerous than is usually suspected. The latter may be summarised as follows:—

1. Natural composition of milk, and in particular its butterfat percentage.
2. Relative freedom of milk from objectionable foreign matter.
3. Presence of undesirable odors or flavors.
4. Abnormal development of common bacteria under the influence of uncontrolled temperatures.
5. Abnormal bacterial contamination.
6. Presence of pathogenic organisms.
7. Presence of adulterants, usually water, but occasionally skim milk.

All these factors join in varying degree to determine the relative quality of milk intended for human consumption, and it goes without saying that apart from factors of natural composition, milk, which is a natural and not a manufactured food product, should be condemned as unfit for human consumption whenever its quality can be shown to be appreciably depressed by the other factors indicated. It is certain, too, that most of the latter can readily be kept under control by the practice of scrupulous cleanliness from the moment the milk leaves the cow's udder to the moment it is delivered to the consumer, by cooling and aerating the milk very shortly after it has been drawn, by maintaining it throughout at low temperatures, and, when necessary, pasteurising and shock-cooling it as a final precaution.

1. *The Butterfat Percentage of Milk.*—Regulations under the Food and Drugs Act, 1908, stipulate that fresh milk shall contain not less than 3.25 per cent. of butterfat, but if artificially heated or pasteurised, not less than 3.50 per cent. It is, however, well known that heavy milkers of some breeds, notably Friesians, yield milk the butterfat percentage of which frequently falls short of the above standards. When milk of this character is intended for human consumption, as such, the only legitimate way of getting over the difficulty is to maintain in a herd a sufficient number of cows with high butterfat percentages, such as Jerseys,

in order to raise the percentage of the herd milk as a whole to the legal standards. To add cream to milk of low butterfat percentage, as is said sometimes to be done, is quite as much a breach of existing regulations as to add skim milk to milk which is deemed commercially too rich in butterfat, which also is said to be done. When, however, wholesale distributing firms secure their milk from various sources, blend it, pasteurise it, and subsequently sell it to retailers, or retail it themselves, no legitimate excuse can be made for tampering with the natural composition of the blended milk. The normal and high butterfat percentages of the majority of the herds will more than make good the deficiencies of a limited number. The only question that arises, in the circumstances, is as to whether milk intended for human consumption should not be purchased by all wholesale firms on the same basis as milk intended for the manufacture of butter or cheese, namely, on weight and butterfat percentage.

In this connection, it may be pointed out that although in South Australia the legal butterfat percentage of milk intended for home consumption is 3.25 per cent. only, Mr. A. J. Cooke, of the S.A. Farmers' Union, Ltd., stated in his evidence that his firm purchased large quantities of milk from the Murray reclaimed land, which carried several Friesian herds, and that the average butterfat percentage of this milk was 4 per cent. On the other hand, the records of the Department of Agriculture show that whilst the milk of individual cows frequently exceeded a butterfat percentage of 6 per cent., in some instances it fell below 3 per cent. Hence, it follows that from the standpoint of butterfat percentages the quality of milk sold to consumers without modification in its natural composition must vary within very wide limits; and since butterfat is an important animal food-stuff, other things being equal, it can be said that the food value of such milk will vary within the same limits. And yet, notwithstanding the fact that the average housewife, when given the choice, will welcome milk from which she can skim off most cream, the back-door price of milk is not based upon its relative food value, but generally upon the minimum figure which the necessities of the vendor enable him to accept. The position is anomalous, and is likely to continue so until such time as the average mind is educated up to a true appreciation of food values.

But if the retail price of milk cannot yet be controlled in this direction, there should be no difficulty in doing so in the matter of wholesale prices. A Victorian distributor informed the Commission that he paid 1d. per gallon more for all milk, the butterfat percentage of which was higher than 4.5 per cent. This may be considered as a step in the right direction, but by no means adequate. Mr. A. J. Cooke, on the other hand, stated in his evidence that his firm had entered into contracts with dairy farmers to pay current Adelaide butterfat prices plus 2½d. per pound of butterfat actually present in the milk. With butterfat at 9½d. per pound and milk averaging 4 per cent., this would represent 3.9d. on butterfat basis, plus 1.1d. bonus, or 5d. per gallon delivered at Murray Bridge. This same milk is subsequently sold as chilled pasteurised milk to vendors at 10d. per gallon. Intervening expenses may be assumed to be—freight, 1½d.; pasteurising, cooling, and handling, 2½d.; or a total of 3½d.; leaving presumably 1½d. to the firm for overhead and profits. Hence, 5d. per gallon at Murray Bridge may probably be taken to represent the parity of 7½d. delivered on the firm's Adelaide premises.

And since under this type of contract, other things being equal, the prices paid for 3 per cent., 4 per cent., and 5 per cent. milk at Murray Bridge would be 3½d., 5d., and 6½d. per gallon respectively, it can be said that the Farmers' Union have introduced a principle into the method of payment of milk intended for human consumption, which is equitably based upon "quality," to the extent that this term discriminates between milks of varying butterfat percentages. The hope may be expressed that other wholesale purchasers will not hesitate to adopt a similar principle.

But Mr. A. J. Cooke added that whilst his firm was purchasing milk intended for home consumption on the above basis, that is to say, paying on weight of milk *pro rata* to butterfat percentages, and complying with all other requirements of the Dairy Industry Act, 1928, some of its competitors operating in the same districts were ignoring butterfat percentages and assessing the quantities to be paid for on the reading of a measuring rod plunged in partially filled cans. Mr. Cooke contended that such actions were unfair to the trade, and contrary to the spirit of the Act, and that existing regulations should be amended in order to check such actions in the future.

In the latter view, however, Mr. Cooke was at fault, since whilst the Dairy Industry Act, 1928, gives ample powers to prescribe special measures for the payment of milk purchased for manufacturing purposes, it gives no powers to prescribe corresponding measures for the purchase of milk intended for human consumption. It is not therefore the regulations that need amending towards that end but the Dairy Industry Act, 1928, itself. At the same time, it can be added to Mr. Cooke's strictures that the use of a measuring rod under the conditions indicated by him is a practice that should be condemned on sanitary grounds.

In this connection your Commissioners are entirely in accord with Mr. Cooke's contentions that the payment for wholesale milk intended for human consumption should be upon the basis of weight of milk purchased and *pro rata* to the butterfat percentage of the milk, and subject to all such other conditions as are prescribed for the purchase of milk for manufacturing purposes. They are of the opinion, however, that these results can best be secured by new legislation for the control of the milk supply of the Metropolitan County District rather than by amendments to the Dairy Industry Act, and they make recommendation accordingly.

It will be obvious that if, as has already been recommended, the minimum wholesale price to be paid for milk by pasteurising plants were fixed by the controlling authority, it would be comparatively simple to provide for the payment of such milk on weight and a butterfat basis. In this connection it would suffice to adopt an average butterfat percentage, say 4 per cent., and stipulate that the metropolitan minimum wholesale price shall have reference to 4 per cent. milk, and that milk of lower butterfat percentages shall be paid for proportionally less, and milk with higher butterfat percentages proportionally more. Thus, if the minimum metropolitan wholesale price of 4 per cent. milk were 1s., the price of 3.5 per cent. milk would be 10½d. and that of 4.5 per cent. milk 13½d.

2. Other Factors in Quality of Milk.—Apart from butterfat percentages, other factors affecting quality in milk are more or less accidental, and for the most part related to the observance or neglect of adequate hygienic and sanitary measures. Important as these factors are—and your Commissioners had ample opportunity to take note of their incidence—it hardly comes within the scope of this report to examine them in detail. In the circumstances it should suffice to stress the fact that notwithstanding the existence for many years past of Board of Health Regulations on the subject, milk intended for human consumption is still being produced, handled, and distributed in South Australia under conditions that are neither hygienic nor sanitary. The comprehensiveness of these regulations may be judged from the preamble to regulation 5:—

“For the licensing of cowkeepers, dairymen, and vendors of milk, the registration and inspection of dairies, milk stores, and milk shops . . . ; and for securing the wholesomeness, cleanliness, and freedom from contamination of milk, and the cleanliness of receptacles, places, vehicles, and vessels used in the preparation, storing, delivering, and serving of milk.”

It was stated in evidence before the Commission that many of these regulations were out of date and could not be enforced, and that those responsible for their administration had been unable to secure suitable amendments. The opinion may be expressed that it is better to have no regulations at all than regulations that cannot be enforced; and it is recommended that all regulations relating to the milk supply of the metropolitan area be revised by the Board of Health in consultation with competent technical officers of the Department of Agriculture and the authority responsible for the control of milk within the metropolitan area.

It should be added that however up-to-date the regulations they must continue more or less dead letters unless enforced by a competent inspectorial staff numerically adequate to the purpose. An inspector, whose training is insufficient to enable him to account for the "why" and the "wherefore" behind each regulation, would be of comparatively little value among a people that does not yet appear to have acquired a milk "sense." Nor can compliance with the regulations become general until inspection of premises is frequent and followed by adequate penalties for ascertained breaches. These observations may be said to apply to the large distributing depots, the dairies, the shops, and farms alike, all of which should be subject to special licences, that can be cancelled for deliberate breaches of the regulations.

At this stage attention may be drawn to certain practices, which although covered in a general way under the heading of "cleanliness," and harmless enough in themselves if strict "cleanliness" be observed, are nevertheless objectionable and even dangerous, because the ideas of "cleanliness" of nine men out of ten are not those implied in the regulations. Practices of this character—some of which will be indicated—should, in the opinion of your Commissioners, be specifically prohibited by regulation, on the grounds that it is not only useless, but dangerous as well, to prescribe regulations for practices which will be rarely, if ever, observed, and the observance of which could never be adequately enforced.

The immersion of any object in milk intended for human consumption is objectionable, but cannot, perhaps, be avoided in special cases as, for instance, when bulk milk is ladled out to the consumer, or when milk is stirred up in order to get even distribution of butterfat. The use, however, of a measuring rod to determine the volume of milk present in partially filled cans; or the use of an ice sleeve to maintain the milk at low temperature should be prohibited.

It would probably be economically unwise to prohibit the use of milking machines; nevertheless, they are sufficiently intricate in structure to render them potentially more dangerous to consumers than the relatively clean hands of milkers. It can be stated that dairymen supplying Nestle's Warrnambool Factory with milk are prohibited by contract from using milking machines. Hence, it is recommended that dairymen supplying milk for human consumption within the metropolitan area shall be prohibited the use of milking machines, unless specially licensed for the purpose. Special rules should be drafted specifying in detail the precautions to be taken in order to keep these machines in hygienic condition, and licences should be liable to cancellation whenever a machine was kept in unfit condition.

In some respects quality is an elusive attribute concerning which the best informed opinions may at times be at variance; in others it admits of strict definition, and has been provided for in existing Board of Health Regulations. For the present, however, the latter do not go beyond questions of chemical composition of milk and prohibited foreign ingredients. It may be suggested here that when these regulations come again under review, as has already been recommended, the advisability of extending their incidence should receive careful consideration. Thus, the relative progress of normal bacterial growth in milk is generally accepted as a reliable measure of the extent to which temperatures have been adequately controlled; and in this connection standards for bacterial count

could be prescribed, or any other standards that might be thought adequate. The presence in milk of tubercle and coliform bacilli should be prohibited. The proportion of foreign matter in suspension allowable in milk should be prescribed. Possibly, too, standards for hydrogen ion concentration could also be specified.

In the above connection it is recommended that the regular collection of numerous milk samples from farms, pasteurising depots, and vendors' carts should form part of the normal routine of inspectorial work. It would probably be in the interests of efficiency if such work were the main occupation of a specially appointed inspector. These samples should be submitted for examination and analysis by competent bacteriologists and chemists. It would be well that the results of these examinations were tabulated and published in the yearly reports of the controlling authority.

Finally, it must be stressed again that in the matter of the milk supply of large centres of population it is inevitable that the wants and health of consumers should receive first consideration, and that suppliers and vendors must adjust themselves accordingly. In the above connection, it is essential that milk supplied should be as free from outside contamination as possible, although it must be admitted that the average consumer does not usually appear to be aware of the fact; but even relative freedom from contamination cannot be insured unless the premises upon which milk is produced are subject to frequent inspections; and the costs of effective inspection become prohibitive when spread over an unnecessarily large number of dairy farms or over an unnecessarily large number of districts. Hence, with the best will in the world, the natural desire of all dairymen within economic reach of the metropolis to share in the advantages of the relatively high metropolitan milk prices cannot be satisfied. The paramount claims of efficient control are so great that the number of licences issued for the purpose will unavoidably be limited. The amount of country milk distributed in the Metropolitan County District in 1932-33 was in the neighborhood of 2,400,000galls. If we assume country dairy farms to yield an average of 6,000galls. per annum per head on the basis of production of the three leanest months of the year, 400 herds would meet the metropolitan requirements, and approximately no more than 400 herds should be licensed.

3. Grade A Milk.—In most large cities there is a limited demand for high quality raw milk produced and handled under conditions that promise almost complete immunity from contamination or from the presence of pathogenic organisms. In New York and other cities milk of this type has come to be known as Grade "A" milk. It is drawn from herds of regularly tuberculin-tested cows, handled under very carefully regulated conditions, and is said to represent from $1\frac{1}{2}$ per cent. to 2 per cent. of the milk consumed in New York.

In England the following grades have been recognised since 1923:—

(1) *Certified Milk.*—Obtained from cows that were tuberculin tested and clinically examined every six months. This milk must show a bacterial count of not more than 30,000, and the Coliform bacillus must be absent in 1/10c.c. of milk. It is bottled on the farm under conditions of strictest supervision.

(2) *Grade "A" (Tuberculin Tested).*—Obtained from cows that were tuberculin tested and clinically examined every six months. This milk must show a bacterial count of not more than 200,000, and the Coliform bacillus should be absent in 1/100c.c. of milk. It may be delivered to consumers in bottles or sealed containers as received from the farm, or in suitable containers of not less than 2galls. capacity, or in bottles with the name of the licensed dealer by whom the milk was bottled.

(3) *Grade "A."*—Obtained from cows that are clinically examined every three months and diseased animals removed. This milk must in all other respects correspond to stipulations indicated for Grade "A" (Tuberculin Tested).

It is suggested that should new legislation be introduced to give effect to the recommendations of this report, special provisions should be made for licensing those who desire to supply Grade "A" type of milk. The conditions under which such milk should be produced and handled should be prescribed in detail, and producers should be given ample protection against unfair tactics of unlicensed dealers or of any others. The controlling authority should also be given power to recoup itself for whatever additional costs might be involved in the supervision of the production and handling of Grade "A" milk.

4. *Standardised Milk*.—Standardisation of milk is a practice which aims at mixing milk containing different percentages of butterfat so that the butterfat content may be averaged to a required ratio. No objection is raised to this practice, unless some butterfat is removed from or added to the milk.

PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR SUMMER, 1934.

EGGS FOR HATCHING AND DAY OLD CHICKENS

WHITE LEGHORNS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, £2 per 100.

DAY OLD CHICKENS.—15s. per dozen; £4 per 100.

BLACK MINORCAS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, £2 per 100.

DAY OLD CHICKENS.—15s. per dozen; £4 per 100.

**Free on Rail,
Salisbury.**

DELIVERY.—CHICKS—February and March.
EGGS—January and February.

Intending breeders should recognise the importance of establishing their flocks with only the very best of stock also, pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2ozs., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

The existing regulations provide that milk sold for human consumption shall be the natural product from which nothing shall be taken and to which nothing shall be added, but the practice of removing some of the butterfat in order to reduce the butterfat content to a definite percentage slightly above the legal limit seems to be generally adopted in many cities.

The arguments in support of standardisation are based upon the fact that of all the component parts of milk butterfat is the one which varies most frequently and within the widest limits. These variations are influenced by quite a number of factors. They depend upon the breed of the cow, the season of the year, the morning and the evening milk, the progress of the lactation period, and the type of food.

Milk is usually purchased by wholesalers on the basis of its butterfat contents, the price increasing as the percentage of butterfat increases, and it is argued that if milk is purchased on such a basis its retail sale price should also be based upon the butterfat content; and that the only practical method of doing this is to fix a percentage of butterfat content for milk for human consumption year in and year out, and blend the milk so as to obtain the percentage and only in this way is the wholesale purchaser able to purchase milk at a price varying with the butterfat content. It is also argued that the value of milk as a food, other things being equal, varies as the butterfat content. The arguments against this practice are:—

- (1) That it is illegal.
- (2) That it is objectionable from the standpoint of the consumer, who would not agree to any interference with the natural condition of the milk.
- (3) That it is dangerous to allow any such tampering with the milk, as it may lead to other interference.
- (4) That the addition of water is the next step.
- (5) That if large distributing firms are allowed to "standardise" milk by the removal of a certain proportion of butterfat from the milk, the same practice cannot be objected to if adopted by the small dairyman, with the result that serious abuses are certain to arise.

In this connection reference may be made to the report of the South Australian Royal Commission on Milk Supply, 1913, issued in November, 1915, which contained the following paragraph:—

"It is also the experience of these cities that this country milk is generally controlled by a comparatively limited number of distributing agencies, and that amongst them standardising is a very general practice. Beyond stating that immunity from detection renders this the most objectionable form of adulteration it is not necessary to here discuss this practice in detail. There is reason to fear that this practice is not unknown in Adelaide, and with the growth of these depots the evil may be expected to grow with them unless effective measures are adopted to prevent it so doing."

At present the legal standard of milk sold in South Australia for human consumption provides for a minimum of 3.25 per cent. of butterfat. It is suggested that the legal limit should be raised to 3.5 per cent., which is the Victorian standard.

Your Commission is not agreed as to whether the practice of standardisation which involves interfering with the natural condition of the milk should be permitted, but if it is the existing law should be amended. It is recommended that power be given to a milk board to make such provision as it thinks fit for the control of blending and standardising of milk which is intended for human consumption.

(To be continued.)

[In the next issue will appear "administrative machinery" to put the foregoing into effect, and "recommendations as to the control of the milk supply." The Commission's report on the butter position will commence in a later issue.]

THE OFFICIAL AUSTRALIAN PURE-BRED DAIRY CATTLE PRODUCTION TESTING SCHEME.

CONDUCTED BY THE DEPARTMENT OF AGRICULTURE, SOUTH
AUSTRALIA.

RULES.

1. The official year shall commence July 1st and end June 30th.
2. (a) Only those cows will be accepted for test which are registered or have been accepted for registration in a recognised Herd Book, Calf Roll, or other Pure Stock Register.
(b) When a breeder owns more than one herd on separate farms, each herd shall be submitted for test and considered and recorded as a separate herd.
(c) Any cow entered for test, and any calf, the progeny of such cow, must be branded to the satisfaction of the Department of Agriculture in such manner as to ensure identification.
(d) Any cow which, on examination, is found to be affected with any disease or condition which may temporarily render her milk injurious may remain in the herd for testing, but her milk shall not be used for sale or for the preparation of any dairy produce for sale without permission.

3. PROPORTION OF HERD WHICH MUST BE TESTED.

All registered cows in a herd which has been submitted for test shall be tested annually unless exempted by the Minister of Agriculture on written application from the owner stating exceptional circumstances and endorsed by the Director of Agriculture, but in no case shall more than 50 per cent. of the females in lactation during each year be so exempted; and, further, all cows must be completely tested at least once before reaching the age of four (4) years, and at least once again before reaching the age of eight (8) years.

4. EXEMPTION FROM TESTING.

Exemptions from the test may be granted in respect of cows which come within the following category:—

- (a) Cows over ten (10) years of age, or those that are sick, diseased, or injured.
- (b) Any cow that aborts during a lactation period shall be deemed to have completed that period at the time she aborts.

5. WHO SHALL BE OFFICIAL TESTERS.

The official testing of cows shall be carried out by qualified officers appointed by the Department of Agriculture. The districts of testing officers shall be changed as often as possible.

6. WHERE TESTING SHALL BE CARRIED OUT.

It shall be optional for officers either to test on the farm or send the samples under adequate protection to be tested at some approved centre, i.e., the laboratory of the Department of Agriculture.

7. COWS TO BE STRIPPED OUT UNDER OFFICIAL SUPERVISION.

The testing officer shall see that all cows are milked out under his supervision at the milking prior to the official 24 hours' test commencing, and shall note the time each individual cow is finished in order that only a bare 24-hour period is allowed.

8. METHOD OF TAKING WEIGHTS AND SAMPLES AND RECORDING SAME.

The milk from each cow under test shall be weighed by the official tester on approved scales, and the weights be recorded. After thoroughly mixing such milk the official shall take samples for the official test. The samples from each milking shall be separately tested for butterfat. The weight and test percentage of each milking shall be recorded separately. No milk weight shall be credited to any cow unless the aggregate of all milkings in the 24 hours totals 4lbs. or over.

9. ACCOMMODATION OF TESTERS.

Every facility is to be afforded by the owners of the herds submitted to testers in carrying out their duties in connection with the scheme, and accommodation provided overnight, if necessary.

10. OWNERS TO PROVIDE TESTING EQUIPMENT.

Owners submitting their herds for testing must provide the necessary Babcock testing machine and equipment if required by the Department.

11. PERIOD OF OFFICIAL TEST.

The official lactation period shall be 273 days, which may be extended to 365 days on the request of the owner. Such request must be submitted in writing to the Department not later than one month prior to the expiration of the 273 days' period.

The official lactation period shall commence FIVE days after calving. The first five days' yields after calving shall not be included in the testing period.

12. COMPUTING OFFICIAL RECORDS.

The yield for the official record shall be calculated as follows:—

(a) The lactation period shall consist in the case of the 273 days' record of nine (9) sub-periods, covering respectively eight (8) sub-periods of 30 days and one (1) of 33 days, and in the case of the 365 days' record of eleven (11) sub-periods of 30 days and one (1) of 35 days.

(b) The cows shall be tested once in each sub-period at approximately equal intervals of time.

(c) The official yield shall be the sum of the yields of each sub-period.

(d) The yield for each sub-period shall be calculated as follows:—

(1) The milk yield shall be the amount of milk yielded over 24 hours multiplied by the length of the sub-period.

(2) The butterfat yield shall be the amount of butterfat calculated by test of the 24 hours' milk yield multiplied by the length of the sub-period.

(e) All cows as far as possible should be tested within the last week of their official lactation period. Cows that are tested for their first sub-period within 15 days after calving must be submitted to ten (10) tests in the case of the 273 days' official period, and thirteen (13) tests in the case of the 365 days' period in place of nine and twelve tests respectively. The ninth and tenth tests and twelfth and thirteenth tests to be averaged. If such cows are not tested during their tenth or thirteenth sub-periods they shall be credited with production for only eight and eleven sub-periods respectively.

13. ISSUE OF RECORDS AND CERTIFICATES.

(a) All calculations shall be made, recorded, and published in terms of pounds of milk and butterfat only.

(b) The Department of Agriculture shall issue certificates showing the records of each cow that attains or exceeds the official standard. Such certificates shall be worded and designed in a manner similar for each State.

(c) The Chief Clerk of the Department of Agriculture shall be also *Herd Testing Registrar*, and shall be responsible for the compilation of records and the issue of the certificates.

Records of all cows submitted to the test shall be published, including all those that fail to reach the official standard. The standards upon which certificates shall be issued are as follows:—

	Butterfat. Lbs.
Junior 2 year old	230
Senior 2 year old	250
Junior 3 year old	270
Senior 3 year old	290
Junior 4 year old	310
Senior 4 year old	330
Mature cows	350

In the above standards a Junior animal in each class is one which at date of calving has not attained to $2\frac{1}{2}$, $3\frac{1}{2}$, or $4\frac{1}{2}$ years respectively, and a Senior animal is one which at date of calving has attained or is over $2\frac{1}{2}$, $3\frac{1}{2}$, or $4\frac{1}{2}$, but less than 3, 4, or 5 years respectively.

14. TESTING AT IRREGULAR INTERVALS.

The tests shall be carried out as far as possible at intervals of 30 days. In the event of it not being possible to do so, the tests may be taken not more than 35 days or less than 25 days after the preceding test; and, if this is not practicable, the calculations for the period under review shall be averaged as in the case of an abnormal test (*vide* Rule 15) except that, in addition to the tests of the preceding and succeeding months, the weights and tests of the sub-period under review, if taken, will also be included in making the average. Additional visits may be made to take supplementary samples at any time considered fit by the Department. Such supplementary samples may be used in place of the original samples if considered advisable by the Department.

15. AVERAGING ABNORMAL TESTS.

When cows on their second or succeeding sub-period tests appear to be in normal health but record abnormally, *i.e.*, more than 25 per cent. above or below normal milk and/or fat yield, owing to being out of condition at the time of the official tester's visit, such tests shall not be registered, but an average made from the proximate and succeeding tests. When the first record is considered to be abnormal it shall be discarded, and the yield for the first sub-period shall be calculated on the average test of the next two periods. Any such abnormality shall be reported to the Department by the official tester. Individual weights and tests of each milking are to be considered separately, and averages shall be struck only for those that are considered abnormal.

16. WHERE FIRST TEST IS TAKEN 35 DAYS OR MORE AFTER CALVING.

Where owners are commencing to test their herds for the first time, or where it has been found impracticable to test certain cows until after they have been calved 35 days or more, the Department may, on the receipt of a statutory declaration from the owner or other acceptable proof as to date of calving, credit the cow's yield with the number of days' production due to her to a maximum of 90 days on the first 24 hours' test made by the official tester.

17. MILKING THREE TIMES A DAY.

No cow shall be milked more than twice per day unless she is yielding more than 60lbs. of milk per day, or unless special written consent is given by the Department. In such circumstances milking three times a day is permitted only until such time as the yield falls to 50lbs. per day, when twice-a-day milking must be resorted to.

18. FEEDING MILK OR CREAM TO COWS.

The feeding of whole milk or cream to cows undergoing test is prohibited as being a wasteful practice. Any records obtained from cows so fed will be disallowed.

19. PARTICULARS REQUIRED BY DEPARTMENT OF AGRICULTURE.

(a) Particulars as to the dates of services, calvings, purchases, sales, deaths, etc., shall be supplied to the official tester, and shall be published if the Department of Agriculture so desires.

(b) Owners must give, on the request of the Department, a declaration as to the class, quantity, or any other details regarding the ration fed during the period of the test, and allow, when deemed advisable by the Department, samples of the different food supplies to be taken for analysis and published if desired by the Department.

(c) All particulars required by the Department concerning any phase of testing shall be made by sworn declaration when deemed necessary by the Department.

20. FEES FOR TESTING.

Each owner shall pay to the Department of Agriculture on entry of his herd and annually thereafter at the commencement of the official testing year a herd entry fee of six pounds ten shillings (£6 10s.). There shall also be paid in advance a fee of ten shillings for each lactation period of each cow submitted for test. The minimum herd entry fee plus testing fees to be paid in advance for each official year shall be eight pounds ten shillings (£8 10s.).

21. TESTING GRADE CATTLE.

The testing officer shall have power to test crossbred or grade cattle when they are the property of members submitting pure breeds, provided he is not unduly detained thereby, but certificates will not be issued for them.

22. DISQUALIFICATIONS, &c.

(a) Should the owner of any herd entered for testing not conform to these regulations, such herd shall be subject to disqualification for such period as the Minister may determine.

(b) The Minister retains the right to refuse to test any herd or to terminate the testing of any herd if in his opinion the rules as laid down have been deliberately broken. The Minister may also refuse to test a herd for any other reason.

23. THE LEGAL ASPECT.

No person who has submitted any herd, cow, or heifer for testing, or for whom any herd, cow, or heifer is at any time tested by the Department, or by any of its officers or servants, shall have any claim for damages, whether arising out of breach of contract, tort, or otherwise howsoever, against His Majesty the King, the Government, or any person in the service or employment of his said Majesty or the said Government, for or in respect of anything done, or omitted to be done, under or in connection with these rules, or the performance, or non-performance, of any act or duty thereunder, or in carrying out or in attempting to carry out the testing of any herd, cow, or heifer, or for anything done or omitted in reference thereto, or in connection therewith.

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on November 29th, 1933, there being present Messrs. A. J. Cooke (Chairman), A. M. Dawkins, R. H. Martin, J. B. Murdoch, G. Jeffrey, F. Coleman, A. L. McEwin, Professor Arthur J. Perkins, and H. C. Pritchard (Secretary). Apologies were received from Messrs. P. J. Baily, J. W. Sandford, and Dr. Richardson.

Next Meeting of the Board.—It was decided that the next meeting of the Board should be held on January 31st, 1934.

Life Members.—The honor of Life Membership of the Agricultural Bureau was conferred on the following members:—Messrs. C. H. Scholz (Pinbong), F. Hassam and L. C. Mann (Milang), H. Paech (Blackheath).

New Members.—The following names were added to the rolls of existing Branches:—Adelaide—Philip Mortimer; Balaklava—G. D. Oster, Howard Wills; Barmera—T. H. Meredith, A. J. West, R. L. Grubb, J. W. O. Carnie, E. Farmer, R. C. Wilson, W. Vasey, T. R. Bawden, W. D. Blight, R. Gaskell, D. Thomas, J. J. Elliott; Belalie Women's—Mrs. Roy Smith, Mrs. I. A. Perkins, Miss L. Crouch; Berri—T. G. Wilkinson, F. R. Clark; Blackheath—Harold Treloar; Blyth—H. Fuller; Coonawarra—R. C. Modistach, Harold Redman, Arthur Hoffmann; Coonawarra Women's—Mrs. G. Hill, Miss D. Modistach, Miss J. Redman, Miss F. Redman; Gladstone Women's—Mrs. E. S. Hillard; Greenock—E. B. Heyne, H. Kernich, F. Parkinson; Kelly—B. J. Miller; Koonunga—J. Neilson; Kybybolite Women's—Miss C. V. Patching, Miss M. C. Johnson; Laura Bay Women's—Miss E. McInerheney; Mangalo Women's—Miss M. Briese, Miss T. Trembath; McLaren Flat—Reg. Rayner, Ray. Beaumont; Milang—E. W. E. Pannell, G. Pannell, R. Pannell; Moorook—E. W. Chaston, Rob. Loxton, L. A. King, R. Moore, D. Thom; Mundalla Women's—Mrs. R. Golding, Mrs. A. Hokin, Miss A. Donnell, Miss E. Donnell, Miss E. Knowling; Narrung—B. Meek, Lewis Thacker (jun.), Roy Dabinett; Penola Women's—Mrs. H. Marks; Penwortham—R. O. Knappstein, P. Wayman; Petina—G. E. Hartree, R. K. Montgomerie; Pinkawillinie—W. E. Enwright, W. Hutchens; Port Elliot—S. D. Bruce; Roseworthy—L. Ey; Saddleworth Women's—Mrs. Friebe, Mrs. Vogt, Mrs. White, Mrs. Burton, Miss F. Bedford; Scott's Bottom—David Fitzpatrick; Tantanoola Women's—Mrs. R. Serle; Wallala—John E. Wilson; Warcowie—C. G. Kittle; Wasleys—J. P. Carrig.

No. of new members for approval, 77; present No. of members, 7,973; present No. of Branches, 334.

A large number of items were taken in Committee.

HOW TO MAKE NEATSFOOT OIL.

The following simple recipe for the manufacture of neatsfoot oil may be appreciated by farmers in view of this oil's value in keeping harness in good order.

Neatsfoot oil is made by boiling in a suitable receptacle the feet and leg-bones (up to the knees) of well-grown cattle. The material should first be thoroughly cleaned by scalding and scraping free from hair, dirt, &c.; it should then be covered with water, which should be brought to the boil and then allowed to simmer for about two hours. After the oil has risen to the surface it should be skimmed off and the mixture boiled again, and a second skimming made.

The oil thus secured should be strained through a piece of cheesecloth in order to extract pieces of flesh, &c., from the mixture, and the strained product should then be boiled again, great care being taken that it does not catch fire. Finally, it should be strained again, cooled, and bottled. Pure neatsfoot oil should be light-lemon in color.

The method described is for manufacture on a small scale; manufacture for trade purposes necessitates the use of a much more detailed and tedious process.—*New South Wales Agricultural Gazette.*

RESULTS AND PARTICULARS OF VARIOUS TESTS ON VINES CARRIED OUT AT BERRI EXPERIMENTAL FARM.

[By N. S. FOTHERINGHAM, R.D.A., Manager.]

For a number of years various tests on vines and trees have been carried out at this institution, and it is the purpose of this article to set down the results of the various tests on vines. The tree or citrus section will be submitted at a later date. In addition to results obtained various observations have been made, and where possible conclusions arrived at have been stated.

TESTS WITH HEAVY BEARING VARIETIES OF VINES.

The vines in the above tests were planted in 1919. The Doradillo was the main variety planted throughout this irrigation area for the production of spirit, and these tests were laid down to see whether a grape of heavier bearing and higher sugar content than the Doradillo could be found suitable to this district. The plot has not been regularly fertilised, and probably accounts for the medium crop averages. With the price of Doradillo grapes at £5 per ton for a 12° Baumé reading, and allowing for an increase or decrease of 5s. per ton per ½° Baumé rise or fall above 12° Baumé there is only one variety that can beat the Doradillo. This variety is Trebbiano, whose gross returns per acre worked out on the above basis would be £34 15s. 6d. per acre, whereas the Doradillo would be £29 7s. per acre. Trebbiano does not hang nearly so long on the vine as Doradillo, and that is an important factor to bear in mind in this area where the time of picking has extended well into June and even later.

FERTILISER TESTS ON VINES.

Previous fertiliser tests carried out at this orchard with Sultana, Currant and Muscat Gordo Blanco vines revealed that of the individual fertilisers supplying either nitrogen, phosphoric acid, or potash the one supplying nitrogen gave far away the best results. This was common to all varieties under test. Besides this fact it was revealed that when nitrogen was in combination either with phosphoric acid, or potash separately or in combination with phosphoric acid and potash, the crop results were much higher than with just nitrogen on its own. Nitrogen was supplied in the form of sulphate of ammonia, phosphoric acid as superphosphate, and potash as sulphate of potash. The maximum quantities of these fertilisers used was sulphate of ammonia 1cwt. per acre, superphosphate (36 per cent. W.S.P) 2 cwts. per acre, and sulphate of potash 1cwt. per acre.

It will be noted that the above were only light dressings, and did not give any indication of the amounts of fertiliser which could be applied to give maximum yields. In consequence of this a further series of fertiliser tests were laid down with much larger quantities of fertilisers per acre. These tests are situated on Block I. of this orchard, and the varieties of vines under test were Doradillo, Currant, and Sultana. Doradillo was substituted for Muscat Gordo Blanco on account of the large area that had been planted in this and nearby settlements. Block I. is situated on the Berri Flat, and comes under irrigation from the 40ft. channel. Its natural vegetation so far as can be gathered was mainly salt and blue bush, with occasional box trees. Small windswept patches were also present. It was originally laid down to lucerne, and carried that crop for approximately 10 years. The lucerne did well on the plot with the exception of the wind-swept patches of soil. This plot, rectangular in shape, was then worked up and laid down to the vines mentioned. The rows of vines were placed 11ft. apart. The plot when planted had first a row of Muscat Gordo Blanco vines, then Doradillo,

Currant, and Sultana, and this order was repeated throughout the plot. The Muscat Gordo Blanco formed a barrier row between each set of three varieties receiving the same fertiliser treatment.

The plot was divided into two portions so that each row had two tests. The distance apart of vines in the row are Doradillo 6ft., Currant 12ft., and Sultana 8ft. Most of the vines were planted in 1921, and the remainder in 1922. A perusal of the accompanying Table I., setting out the results of these tests, will show the amounts of fertiliser used per acre, and it will be seen that superphosphate and other fertilisers are applied in much larger quantities than in the early fertiliser trials which have been mentioned. In addition to this bonedust which mostly supplies phosphates is in comparison with superphosphate, and similarly nitrate of soda is compared with sulphate of ammonia, muriate of potash with sulphate of potash. Besides these there are various combinations of these fertilisers, green manuring with legumes, gypsum, sulphur, and no-fertiliser plots. There is no intention yet to try and make any comparison of the effect of the various fertilisers used.

It is indeed unfortunate that the ground on which these tests were set out was previously under lucerne. The lucerne has enriched the soil with nitrogen, and even the no-fertiliser tests are showing good yields. In fact the only tests showing poor yields are those which have been planted on wind-swept patches of soil and on which the lucerne itself did not grow well.

TABLE V.—RESULTS OF VINE

Row Nos.	Method of Training.
1 and 2	Each vine trained as an Espalier with one pair of arms. Vines trained alternately on bottom and middle wire. Spur pruned
3 and 4	Each vine trained as a Cordon. Spur pruned. Vines trained alternately on bottom and middle wire
13 and 14 . . .	Each vine trained as an Espalier with a pair of main arms set on the bottom and middle wire. Spur pruned
15 and 16 . . .	Each vine trained as an Espalier with a pair of main arms set on each wire. Spur pruned
25 and 26 . . .	Trained on T trellis as Espalier with one pair of main arms trained on a central wire running through post 6ins. below T piece. Spur pruned
27 and 28 . . .	Each vine trained as a double parallel cordon, the main arms being set on wires in T pieces. Central wire if trellis is 6ins. higher than side wires. Vines spur pruned
29	Each vine trained as a Cordon on T trellis. Main arms are formed on a central wire which is 6ins. higher than side wires. Rod and spur pruned

TABLE VI.—RESULTS OF VINE

Row Nos.	Method of Training.
5 and 6	Vines trained as Cordons. Main arm set on central wire. Fruiting canes lifted and tied to top wire. Rod and spur pruned
7 and 8	Vines trained as Cordons. Main arm set on central wire. Fruiting canes depressed and tied to bottom wire. Rod and spur pruned
17 and 18 . . .	Vines trained as Espaliers. Main arm set on central wire. Fruiting canes lifted and set on top wire. Rod and spur pruned
19 and 20 . . .	Vines trained as Espaliers. Main arm set on central wire. Fruiting canes depressed and tied to bottom wire. Rod and spur pruned
30 and 31 . . .	Vines being reformed to Cordons on T trellis. Rod and spur pruned
32 and 33 . . .	Vines being reformed to Espaliers on T trellis. Rod and spur pruned
34 to 37	Vines trained as Bordelais Espaliers. Fruiting rods horizontal. Rod and spur pruned

CINCTURING TESTS ON CURRANT VINES.

It is well known that until the cincturing of the currant vine was adopted in South Australia the crops obtained were very light. The practice of cincturing is now general wherever currants are grown. There were aspects of this practice, however, that required investigation, and tests were set out to see whether:—(a) The nature of the cincture, i.e., whether made with a single knife cut around the stem of the vine, or whether made with a double knife cut about $\frac{1}{2}$ in. wide around the stem and the strip of bark removed, had any effect on the ultimate yield. (b) Another aspect was the consideration of the time or period of flowering at which the cincturing was performed.

The table below shows the tests carried out to try and determine the aspects just mentioned. The results so far indicate that a cincture made with a double cut and the strip of bark removed has a greater yield at all periods of cincturing than when only a single cut is given. They also disclose that it is better to cincture early than late.

CINCTURING TESTS ON SULTANA VINES.

Unlike the currant cincturing of the sultana vine is not necessary to obtain a good setting of berries, but it was thought that increased returns may be gained by the cincturing of this vine. Tests on somewhat similar lines to those practised on currants were laid down, and the results are tabulated below. The main point found out from these tests is that, where the Sultana vine is both cinctured and topped the vitality of the vine is considerably weakened so much so that it is now difficult to find suitable rods to furnish the succeeding crop, and in consequence its yield is low. The uncinctured row with which the cinctured tests were to have been compared was an outside row, and obviously held an unfair advantage over the cinctured tests, and is therefore not tabulated. Nothing definite can be established as to whether a single knife cut is advantageous over a cincture made with a double cut about $\frac{1}{2}$ in. wide with a strip of bark removed or *vice versa*, nor do the tests disclose anything definite regarding the time at which the vines are cinctured.

VINE TRAINING TESTS ON CURRANT VINES.

When this institution was established in 1911 the main varieties of grapes grown under irrigation were the Currant, Sultana, and Muscat Gordo Blanco. These were all grown for drying purposes. Various systems of training were used on these three varieties. Each variety will be treated separately.

CURRANTS.

The two main systems used in the trellising of the Currant vine are the espalier and the cordon. There were in the tests, however, modified forms of both these systems, and these are described in the accompanying results. In all tests with the exception of Row No. 29 the vines were all spur pruned; with this row, however, they are rod and spur pruned. The general conclusions that can be deduced from these results after a long period of years are:—(a) That the espalier trained spur pruned vine will give higher yields than a spur pruned Cordon trained vine. (b) That espaliers trained with two pairs of arms—viz., Rows 13 and 14—give higher yields than (a). (c) That espaliers trained with three pairs of arms—viz., Rows 16 and 16—give higher yields than the systems mentioned in (a) and (b). (d) That Currant vines trained as a cordon on a T trellis—viz., Row 29—and rod and spur pruned give slightly the highest yields of any. It is to be noted, however, that the fruit on the rod and spur pruned cordon trained vine is not nearly so bold as the fruit from any other spur pruned test, and that there is a large percentage of red berries—a type of Currant that is not wanted.

The vines in all these tests have been treated similarly except with the pruning and training. They had not until 1928 received definite yearly fertiliser treatment. It is intended at a later date to compare the yields since regular fertiliser dressings have been applied with the yields prior to that date.

TRAINING TESTS ON SULTANA VINES.

Unlike the Currant this vine does not usually produce fruit on spurs, and in consequence rods have to be relied on for the fruit-bearing wood. Odd spurs are, however, left to provide rods at suitable positions for the following year's crop. It will be noticed in the results that the depression of fruiting canes or rods is tried against the elevation of the fruiting canes or rods in two instances—viz., 7 and 8, v. 5 and 6, Rows 19 and 20, v. 17 and 18. In the first instance there is practically no difference in yield, whereas in the second instance there has been an increase of approximately 16 per cent. in favor of depressing the fruiting canes or rods. The other tests are relatively close to one another, and in no cases are the rods depressed.

In these times of fairly heavy fertiliser dressings and consequent strong growth the numbers of rods or canes left during pruning has been much increased, and it is not advisable to wrap all the canes or rods on one wire, as it leads to crowded foliage with its attendant danger of fungus disease, crowded and tangled fruit, which is difficult to pick and gets damaged in doing so.

TRAINING TESTS ON MUSCAT GORDO BLANCO VINES.

This vine produces the main quantity of Lexias or pudding raisins, besides being used as a wine and spirit grape. So far as trellising tests are concerned we find that the Thomery espalier trained spur pruned vine gives much higher returns than the cordon or bush trained vine, whether rod and spur pruned or open pruned to spurs of one bud. The fruit in all tests is very good, but it has to be stated that the fruit from the bush trained vine spur pruned to one bud yields fine large and bold fruit eminently suitable for high-class table raisins. The results of these tests are in the table following.

**TOP SPECIAL (45%)
And 48% MINERAL**

S. Garrard, Farrell's Flat—Gallipoli.

F. Coleman, Saddleworth—Nabawa, Waratah, Tuela x Ford, and Gallipoli.

FLINDERS—

R. Kain, Yeelanna—Waratah, Gallipoli.

W. Watkins—Ford.

*Owing to the quick ripening of the crops in these districts the judge states that grading will be necessary in these seed wheat crops to eliminate pinched grain.

OATS.

Mr. E. L. Orchard advises that he inspected oat crops on the farm of Mr. F. J. Pedler, Koolunga, and reported that crops of Guyra and Mulga oats were suitable for seed.

MIDLAND DISTRICT—

G. Hazel, Kapunda—Palestine.

C. H. J. Behn, Riverton—Calcutta Cape and Imbros Island.

F. Coleman, Saddleworth—Calcutta Cape.

EXPERIMENTAL FEEDING TESTS CONDUCTED AT PARAFIELD POULTRY STATION.

[By C. F. ANDERSON, Poultry Expert.]

A series of feeding tests are being conducted at Parafield Poultry Station with a view to ascertaining if suitable foods which are obtainable on the majority of our farms can be satisfactorily fed to poultry. The tests are each of 50 White Leghorn pullets, and commenced on April 1st, 1933.

The feeding is as follows:—

No. 1 Test.—Morning—Wet mash composed of 1 part crushed barley, 2 parts wholemeal (by weight), $\frac{1}{2}$ lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird.

Night—1oz. wheat per bird.

No. 2 Test.—Dry mash composed of same proportions as No. 1 Test.

Midday—Greenfeed.

Evening—Wheat.

No. 3 Test.—Morning—Wet mash composed of 1 part bran, 2 parts pollard (by weight), $\frac{1}{2}$ lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird.

Night—1oz. wheat per bird.

No. 4 Test.—Morning—Wet mash composed of 1 part bran, 2 parts wholemeal (by weight), $\frac{1}{2}$ lb. meat meal, 50 per cent. chaffed greenfeed.

Midday—1oz. wheat per bird.

Night—1oz. wheat per bird.

No. 5 Test.—Morning—2ozs. wheat per bird.

Evening—2ozs. wheat per bird.

Greenfeed in season.

The following are the numbers of eggs laid by each pen from April 1st, 1933, to October 31st, 1933.

Definite conclusions, however, cannot be given at this juncture with regard to the various methods of feeding. It is necessary for the tests to complete the 12 months before any satisfactory opinions can be formed.

DAIRY AND FARM PRODUCE MARKETS.

MESSRS. A. W. SANDFORD & Co., LIMITED, reported on December 1st, 1933:—

BUTTER.—Trading in this commodity throughout November was very difficult indeed, for, owing to the Commonwealth Dairy Produce Control Board having fixed prices above parity, the shipments had to go forward on consignment, and when these reached Britain, values had slumped badly. The result was that heavy losses were incurred, for the butter should have been sold at considerably higher prices than it subsequently realised. Production is now declining steadily, but this is the usual seasonal happening. Local values were maintained, but there were heavy quantities which were sent forward each week to Britain. Choicest creamery fresh butter in bulk, 1s. 0½d.; prints and delivery extra. (These prices are subject to the stabilisation levies.) Store and collectors', 4d. to 4½d. per lb. at store door, less usual selling charges.

EGGS.—Exporting of eggs continued throughout the month, and all which would pass the graders for export were sent forward from week to week. Supplies have now declined rapidly, so that within the next few weeks shipments will have about ceased. In the meantime there is a better local demand and all lots are being cleared readily. Prices for export came back and ordinary eggs maintained. Ordinary country eggs, hen or duck, 4d. per dozen; selected export quality eggs, 1½ozs. and over, 8d. to 8½d. per dozen.

CHEESE.—Heavy quantities came forward from the South-Eastern factories each week which were satisfactorily placed to local and Western Australian buyers. The easing in rates caused heavier buying on the part of local traders and the market is sound. New makes, large and medium, 6½d. to 6¾d.; loaf, 6½d. to 7½d.; semimatured and matured, 9d. to 9½d. per lb.

BACON.—The consumption of bacon throughout the month was maintained on an average level, although during warm spells the trade fell away a little, but recovered as soon as cooler conditions prevailed. Heavy quantities of hams were placed both on spot and for forward delivery for Christmas trade. Best local sides, 9½d. to 9¾d.; best factory cured middles, 10½d. to 11d.; large, 9d.; rolls, 8d. to 8½d.; hams, 1s. to 1s. 0½d. per lb.; cooked, 1s. 2d. to 1s. 2½d. per lb.

LARD sold steadily at quotations. Prints, 7s. per dozen.

ALMONDS were marketed in greater quantities last month, and where the quality was satisfactory prompt sales were made in the open markets, but small and stained consignments were not readily quitted. Kernels came forward in fair supplies and were sold satisfactorily. Softshells and Brandis, 8½d. to 9d.; hardshells, 5d. to 5½d. per lb.; kernels, 1s. 11d. to 1s. 11½d. per lb.

HONEY.—Except for the local trade there has not been much turnover, interstate buyers operating only sparingly. Heavy quantities are now coming forward of the new season's "take," and the quality generally is satisfactory. Rates are steady. Prime clear extracted in liquid condition, 3d. to 3½d. per lb.; lower grades, 1½d. to 2½d. per lb.

BEESWAX.—Manufacturers purchased rather more freely throughout November and there was no carry-over of stocks, consignments being quickly cleared at quotations; 1s. 0½d. to 1s. 2d. per lb. according to sample.

LIVE POULTRY.—The supplies of live poultry are now coming along in increasing quantities each week. Although consignors were advised to not delay the forwarding of birds, during November the markets were bare. However, it is expected that a good demand will continue right up to Christmas, and it would be advisable to market stock promptly to obtain best results. We advise consigning. Crates loaned on application. Prime roosters, 4s. to 5s. 6d.; nice conditioned cockerels, 3s. 5d. to 3s. 11d.; fair conditioned cockerels, 2s. 9d. to 3s. 4d.; chickens lower. Heavy weight hens, 2s. 5d. to 3s. 3d.; medium hens, 1s. 8d. to 2s. 4d.; light hens, 1s. to 1s. 7d.; couple of pens of weedy sorts lower. Geese, 3s. 6d. to 5s.; goslings lower. Prime young Muscovy drakes, 5s. to 6s.; young Muscovy ducks, 3s. to 3s. 11d.; ordinary ducks, 1s. 3d. to 2s. 6d.; ducklings lower. Turkeys, good to prime condition, 10d. to 1s. 3d. per lb. live weight; ditto, fair condition, 8d. to 9d. per lb. live weight; ditto, poor and crooked breasted lower. Pigeons, 3½d. to 6d. each.

POTATOES.—Old, 4s. 9d. per cwt.; new season's, 9s. 6d. per cwt.

ONIONS.—New season's white, 6s. per cwt.

RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department show the rainfall at the subjoined stations for the month of November, 1933, also the average precipitation for November, and the average annual rainfall.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[Branch Secretaries are reminded that the following are exempt from payment of the Annual Bureau subscription:—Life members, Branch Secretaries, members appointed before August 1st, 1930, and new members who reside in the same house as (a) a life member, (b) Secretary, or (c) another member who already subscribes.

The subscription for all other members is 2s. 6d., commencing from August 1st in each year, provided that—subject to the above exemptions—nominations forwarded during the months of January to June must be accompanied by a payment of 1s. 6d. each nomination for that period.]

MEN'S BRANCHES. SOUTH-EASTERN DISTRICT.

FRANCES (Average annual rainfall, 19.99in.).

September 6th.—Attendance, 9.

PASTURE IMPROVEMENT.—Mr. Herold read the following paper:—"The practice adopted on our farm to improve the pastures has been to sow subterranean clover with the crop, cropping a fresh piece of land each year. The land is worked to a smooth bed, and the seed drilled to a depth of 1in. to 1½in. to avoid burying it too deeply. The clover seed is mixed with the grain and sown at the rate of 1lb. of clover per acre, which gives an adequate covering the first year. First-grade seed is always used because it gives a better return for money expended, and is also free from weeds. The following year the paddock is top dressed, sown with half a bag of superphosphate to the acre, also the next year and the third year after sowing. Top dressing is then left off until the paddock shows signs of going back, when superphosphate is applied again. Over top dressing is not a wise plan, because too many sheep have to be kept in the paddock to keep the grass from becoming rank, consequently the pasture is dirtied by the continual droppings of the sheep, and the surface of the land becomes spongy, similar to a sheep camp. Paddocks in this condition provide a harbor for lucerne flea, &c. To overcome this it is intended to re-plough such paddocks and re-sow them with perennial rye grass and *Phalaris*, there being still enough clover left to make an even ration of itself to mix with the other grasses." (Secretary, C. Koch.)

MILLICENT (Average annual rainfall, 29.76in.).

August 25th.—Attendance, 11.

QUESTION BOX.—Mr. G. Chapman sought information as to the best months for the joining of ewes and rams and the number of ewes to allot to each ram. Mr. H. Hutchesson preferred about the end of January. He usually allowed about 70 ewes for each ram. Mr. G. Major said he had generally made a practice of running 50 ewes to each ram. It was often found that rams knocked each other about fairly badly by fighting, and joining in separate lots of, say, about 75 ewes to each ram, was a good practice where that was practicable. He had tried yarding at night and found it beneficial. He usually left the ewes with the ram for six weeks exactly. If they were there longer, the period of lambing was not sufficiently uniform. Mr. K. Skeer asked at what age it paid best to dispose of fat lambs. It was the general opinion that it was good policy to avoid holding lambs beyond a reasonable selling age. There was always the risk that they would deteriorate beyond a certain age and weather conditions often had an adverse effect. Mr. H. Hutchesson asked for information as to the effect a heavy dressing of super would have on potatoes so far as blister was concerned. Mr. K. Skeer said blister was a condition arising from the nature of the ground. An insect lodged there and got into the potatoes. No ill-effects followed planting seed with blister. Clean plants resulted. However, blister would continue if planting was repeated in a paddock where it had once been noticed. In a particularly good season it might be avoided. Mr. A. Sapiatzer referred to very beneficial results that had been obtained in ridding land of blister tendencies. He advised the sowing of pease and rye and ploughing them in again at a very early stage. A variety of opinion on the subject of pickling of wheat and barley was forthcoming when Mr. Skeer brought up

an experience where, using a petrol drum, bluestone had escaped through the iron. Mr. Watson said he had tried pickling in these drums and had found barley results satisfactory, whereas there was only poor germination of the wheat. He accounted for the trouble as due to rust off the iron. Mr. Chapman advised the use of wooden receptacles only, and pickling in a preparation of 1lb. bluestone to 10galls. of water. Mr. Skeer advised the same consistency for barley and 16galls. of water to the same amount of bluestone for wheat. Mr. H. Hutchesson said he had secured good results from dry pickling wheat. Mr. Skeer said farmers were assured that bluestone pickling was only of benefit in combating ball smut. That was not present in local crops of barley, and as the process was not meant to deal with loose smut, what was the use of pickling barley? Mr. L. Hateley thought pickling was warranted. They always used a strong solution of 1lb. bluestone to each bag of barley. (Secretary, I. Hutchesson.)

IMPORTANCE OF GOOD QUALITY CREAM.

[Paper read by W. H. Downes (District Dairy Instructor) at the August meeting of the Coonawarra Branch.]

Owing to the comparatively restricted demand on the local market for dairy produce, and also because of the fact that supplies will soon be rapidly increasing, butter production will quickly exceed the normal requirements of the State. Immediately this occurs it will be necessary to export our surplus supply, and this is usually forwarded to the London market. Unfortunately this appears to be about the only available market remaining at the present time to which exporting countries may send their dairy produce. While capable of absorbing enormous quantities of this commodity the tremendous increase in dairying during the last few years has had the effect of heavily overloading this once so favored outlet to the extent of saturation point. Buyers in the trade, therefore, are able to be far more discriminating with regard to butter quality than was the case a few years ago, and the quality naturally needs to be very sound before they will buy. The rapid strides made in the improvement of buttermaking machinery, together with advanced scientific methods, have enabled most modern factories to overcome faults in manufacture which were previously common, but now are of comparatively rare occurrence. Unfortunately factory progress—great though it has been—does not overcome the grading problem, nor the necessity to keep up the standard of quality by this means. In order that factories may successfully compete in interstate trading, and be able to produce an article fit for exporting overseas, suppliers as a whole may expect a general tightening up in grading methods very shortly. It will be essential in the butter factories' interests to carefully grade all cream received, and there is little doubt that a fair percentage of cream, mediocre in quality, previously paid for as "Choice" will be reduced to either First or Second Grade. A supplier who receives notice that his cream is of inferior quality naturally feels upset, besides having to accept a lower rate for his produce. He may naturally think that he is being treated with undue harshness by the factory, but there is usually a very good reason for the fact that his cream has been graded down. While our sympathies extend to the man who is making a genuine effort to improve the quality of his cream it must not be assumed that the factory grader is at fault. Indiscriminate grading down of cream would quickly result in a depleted supply, which would not be in the best interests of the factory concerned. With the approach of warmer weather it will be more difficult for some suppliers to consistently receive the top grade price for their cream, unless they adopt the necessary measures to ensure that their produce is of sound quality.

The principal faults noticed in local cream are chiefly due to defects in flavor. These can be summarised as follows:—

Stale Flavor.—This is one of the most common defects noticed in South Australia, and is chiefly responsible for the fact that South Australian butters have not enjoyed the best reputation in past seasons. It is due to the fact that cream is kept far too long on the farm before being delivered to the factory, to such an extent that occasionally it is bordering on rancidity by the time it reaches its destination. While transport difficulties and small supplies of cream may be to blame for a good proportion of this trouble they are not responsible for all of it; quite often it could have been avoided if suppliers as a whole would realise the necessity of forwarding their cream in as fresh a condition as possible. This point will easily bear stressing, because by so doing the producer will greatly assist the factory in the production of a better article as well as enhancing his own prospects of receiving choice prices consistently.

Sour or Over-ripe.—This flavor is due to the presence of too much lactic acid in cream. Factors responsible for its occurrence are too low a test, warm conditions, and age. In the course of a little time a stale and cheesy flavor usually develops.

Fermented Flavor.—This may be due to several causes, the chief of which are enumerated:—(a) Cream kept too long, not in the best condition, particularly if it is low in butterfat test. (b) Mixing together cream of different temperatures before the warmest has cooled sufficiently. (c) Using a separator twice a day and only washing it once, or if washing it on each occasion the washing and scalding of the various parts is inefficiently done. (d) Keeping the afternoon's milk overnight and heating it up the following morning for the purpose of separating.

Tallowy Flavor.—This is a chemical taint noticed most commonly during warm weather. Though not confined to creams of high test it is, however, more frequently found in cream high in butterfat content. It develops as a result of cream becoming exposed to heat, or being air dried on the surface, as a consequence of which the chemical nature of the butterfat is permanently altered. It usually becomes more pronounced with age, and the process of pasteurisation, rather than producing an improvement, tends to increase this defect.

Metallic Flavor.—This is another chemical flavor which usually, though not always, is associated with low testing cream. It is produced as a result of the lactic acid contained in the cream coming into contact with certain metals. It will rarely occur if the separator parts and other utensils, buckets, cans, &c., are well tinned and kept well washed. Any neglect in either direction will soon be productive of this characteristic taint, which is another flavor that cannot be removed by pasteurisation.

Feed Flavors or Fodder Taints.—All green fodders when fed to cows have the effect of tainting milk to a certain extent, but while some are mild and not unpleasant others are so strong and objectionable as to be easily noticed in the milk. It is advisable to avoid feeding cows on fodder of a strongly tainting tendency where possible, provided the milk supply is not seriously affected by so doing. Nevertheless they cannot always be avoided, particularly as much of the South-Eastern pastures contain a big sprinkling of clovers. Under these circumstances the potency of these flavors may be reduced considerably by judicious feeding, aeration, and stirring. By turning cows into pastures of this sort immediately after milking, removing them a few hours before next milking, by cooling and aerating as well as daily stirring all cream, a vast improvement in the flavor will be immediately noticed.

Absorbed Flavors.—It is surprising how quickly cream absorbs and retains certain odors, especially when articles possessing pungent aromas are placed near it. Probably the best point to illustrate this tendency is demonstrated by the fact that timber used in butter boxes must be carefully selected and free from any resinous smell or timber taint. It is essential, therefore, that cream should be kept a reasonable distance away from anything likely to affect the flavor in this way.

While the various taints in cream have been mentioned and described singly, it is quite possible for cream to possess a combination of two or more flavors, such as stale and tallowy, sour and fermented, &c., the nature and extent of which will naturally depend upon the conditions under which it was produced, the treatment it receives on the farm, and the method of delivery, &c. As a factor of considerable importance to improved quality the regular, frequent delivery of cream should be once more stressed. The primary cause of inferior quality in South Australia is the usual tendency on the part of many suppliers to hold their cream too long. New South Wales several years ago took the drastic step of inaugurating a system of daily cream supplies, with the result that fully 95 per cent. of her manufacture to-day is of "choice" quality. In a State where summer temperatures are not conducive to good cream quality this may be regarded as a remarkable achievement, but in South Australia, where summer conditions are so much better, it would appear possible to better even these figures if the dairying community as a whole saw fit to discontinue depending on good weather conditions as a means of preserving their cream quality.

The supplier who takes a pride in his produce and who continually aims at securing top prices will be well advised to cool his cream during warm weather. This should be accomplished by the best means at his command, but for preference a proper water-cooled cream cooler and aerator are to be recommended. The low temperature thus attained will quickly check any bacterial development, and thereby considerably enhance the keeping quality. Stirring two or three times daily will tend to minimise any objectionable "feed" flavors present in the cream.

Cleanliness in every branch of the work is naturally of paramount importance if the best quality cream is to be produced. For this reason suppliers who are not in the habit of washing their separators each time they are used are strongly urged to do so. Rinsing dairy appliances in warm water alone is not conducive to satisfactory results. After being well scrubbed and rinsed all dairy utensils should be thoroughly scalded with boiling water. This latter treatment will eliminate many of the troubles

that cream is heir to; it kills all germ life present in or on the surface of these utensils as well as ensuring rapid drying, which will minimise the danger of further bacterial development. The remark is sometimes heard from men who evidently have not studied the question that the price of butterfat at the present time does not warrant any extra care or treatment of the cream. With markets glutted and a poor demand for dairy produce as a whole it is essentially the time for us to concentrate on sound quality, so that we have reasonable hopes of disposing of it at a decent price. Otherwise if the quality is to remain indifferent the possibility of selling is extremely limited, and then at a price totally inadequate for the work and toil connected with dairying.

Unfortunately South Australian butter is not in keen demand, due no doubt to the practice of incorporating too much cream of inferior quality in the choice butter in order that choice prices could be paid all round. The natural consequence has been to build up a well-earned prejudice against South Australian butter in a general way, and this is going to take some time to break down. Unfortunately, also, the careful cream supplier has been penalised to some extent by the careless man during the process, so that it is much to the interest and advantage of the former that stricter grading at factories be rigidly observed and insisted upon.

DUCK RAISING FOR EGG PRODUCTION.

(Paper read by Mr. V. Smith at the September meeting of the Bendelsham Branch.)

This district is ideal for raising ducks for egg production. I favor the Fawn and White Indian Runner duck. When starting to raise ducks for egg production it must be realised that the care of the birds will involve a fair amount of time and work. Any person who thinks money is to be made out of poultry of any breed without the above is foredoomed to failure. One sees many small flocks of ducks. For several years numerous arguments have been advanced as to the advantages of ducks over hens in this district. I have produced more eggs in the last three months from 90 ducks than any one farm in the district, and some of the farms have upwards of 300 hens. This has not been accomplished without a fair amount of hard work and special feeding.

HATCHING.

When starting out to breed ducks the first question to decide is whether hens or ducks are to be used for hatching. It is definitely not possible to rear ducklings successfully if both hens and ducks are used in the hatching of them. The duck fouls the water very quickly, and so causes diseases amongst the ducklings if the water is stationary. The only way to prevent the water fouling is to have a running stream for the ducklings into which the mother duck cannot enter. A flushing of all watering utensils with a bluestone solution is essential and prevents much disease. This should be carried out every day. I prefer hens for hatching, because they are usually more reliable in completing the job. Moreover, in cold weather a hen will mother her brood and cover them and so keep them warm. I have had as many as 60 hens sitting on duck eggs in one shed, but found it a very costly blunder, especially where pullets were sitting near aged hens. I lost many settings of eggs due to pullets not returning to the right nest after leaving to feed. They often sneaked into an old nest, and when the old hen returned she forced her way into the same nest. This left the pullet's setting of eggs to spoil. In handling such cases be very careful and kind in handling the pullets, otherwise they will refuse to settle down again. A good plan is to place a bag over the box for a few hours after replacing the pullet. Do not use pullets if it is possible to avoid doing so.

When setting duck eggs always place them on the ground. A few handfuls of dry straw will help to keep the eggs clean underneath. The moisture drawn from the ground is essential to the incubation of the eggs. No harm will be done if a good, quiet sitter is lifted off the eggs every few days and lukewarm water sprinkled over the eggs. This applies especially to summer hatching, and in this district it is usually late spring or early summer when most broody hens are available.

FEEDING.

Before starting to set the hens see that there is a plentiful supply of the various green feeds—chou-mollier, mangolds, lettuce, silver beet, &c. If these plants are well grown when the ducklings are hatched, at least half the food problem will be solved. Ducklings are gross eaters of green food, and thrive on it. A good method of preparing the food is to use a large sized mince, as used for household purposes. Pick a good supply of fresh young leaves off the various plants, then add a dozen rabbits' livers, and put the lot through the mincer, afterwards adding sufficient bran and pollard to make the mixture into a crumbly mash. A sloppy mash is not suitable for ducklings. Forty per cent. of green feed can be used in cold weather and up to 60 per cent. in hot weather. If kept in a cool place a hopper containing about 10lbs. of this mixture will keep at least 50 ducklings up to three weeks old busily engaged all day. Chaff up an extra hopper of green feed and place it handy to the mash hopper. As the ducklings grow, the quantity must be increased, but the same methods can be continued.

Never give the ducklings free access to swimming water until at least one month old, otherwise losses from cramp may occur. Never place more than 20 to 30 ducklings in the same pen, as they will crowd under and around the hens, and many will be smothered. If four hens are set on one dozen eggs each, they should be all placed in a pen at one time, and all other stock kept away from them. They will not then be likely to return to a different nest after coming off to feed. Another advantage is that there will be sufficient ducklings of the one age to place in a pen of their own. Allowing for infertile eggs, and the usual casualties, about 30 to 35 ducklings should be hatched. As these will be hatched in fairly warm weather, three large hens, such as the utility Black Orpington, will cover the ducklings until old enough to fend for themselves. This means that the extra hen can be kept in a coop until she has ceased being broody, and so have her back laying some time before the other hens.

After about four weeks in the pens the ducklings can be given free range in the green-feed plots, and they will pick up a considerable amount of grubs and insects besides having a plentiful supply of green feed always fresh and palatable. The meat

or liver supply can now be reduced by half, and a little crushed wheat supplied in hoppers placed where the hens cannot reach it. A pen of 3in. netting will serve that purpose. When the drakes are about 12 weeks old they should be disposed of; this class of drake is rather small and does not pay to hold above that age. If they can be sold for 1s. 6d. per head locally, it is a better proposition than sending them to the city markets.

If a duck commences laying at about eight months old that is near the average age for a well-bred bird. A flock of ducks usually starts laying in a fair average number, all within a few weeks, and will cease almost as quickly. This is a decided advantage, because it saves penning off non-layers from layers, and saves two different diets being prepared; food used for fattening or growing purposes is unsuitable for laying birds. The latter naturally needs the more costly foods, and must have it if a profit is to be shown. I usually joint about 12 to 15 rabbits and boil them for one hour in a kerosene bucket. I then add about 6lbs. or 7lbs. of malting barley, and allow it to simmer for half an hour. If this is done in the evening the food is usually warm next morning. I then add about 5lbs. or 6lbs. of bran and half that amount of pollard, placing the whole in a tub. This is mixed thoroughly with a shovel, and placed on clean sheets of galvanized iron. This quantity will feed about 90 to 100 ducks. A supply of fresh water should be placed handy so that the ducks may wash their beaks out occasionally during the meal. It will be noticed the ducks will make frequent excursions to the water trough to wash their beaks out if the water is close handy. The ducks are then allowed out of the pen all day. At evening feed I give them the dry grain, on an average about 1½ozs. per bird. They are again penned up at 9 p.m. for the night. Clean drinking water deep enough for a duck to immerse its eyes should be supplied both day and night. The free use of a bluestone solution will keep the water pure and keep disease down to a minimum.

If egg production is profitable then why not devote the same attention to it as one would to any other class of farm produce. Egg production in the lower South-East is profitable, and more so than most other farm produce at present ruling prices. If one breeds a good class of duck, such as the Fawn and White Runner, they should commence laying in early April, when eggs are at their highest, and continue laying consistently until the end of October, and even longer. With normal seasons and prices one should average at least 1s. per dozen. Those facts, if worked out, should be convincing proof that there is a profit in ducks. (Secretary, F. White.)

VISITING DAYS AT KYBYBOLITE AND BERRI.

Visiting days at Experimental Farms are functions somewhat similar to the popular homestead meetings which most Branches of the Bureau arrange annually. At homestead meetings members have an opportunity of seeing what the other man is doing, gaining information and where appropriate offering advice. The additional advantage of such meetings at Experimental Farms is that first hand information may be gathered in connection with experiments and the benefit of this applies in a special manner when there is a near relationship between the work of the experimental farm and the work on the farm of the visitor. It is not surprising therefore to find that Bureau members and others attend these visiting days in large numbers for the purpose of seeing for themselves the results of experiments and of ascertaining the progress of trials intended to solve local problems which arise from time to time and which are subjects of constant discussion at Branch meetings.

Within recent years there has not been any lack of public interest in the work of farms under departmental control. It may even be said that such interest has increased: at all events, it can be inferred from recent attendances that farmers continue to recognise the value of experimental work and that no matter what set of conditions may occur—whether prices be high or low, or yields good or poor—the need for experimental and research work will always exist. Furthermore, the large attendances reported from visiting days manifest confidence in administration and are signs that the farming community realise that these farms are fulfilling—or are attempting to fulfil—the objects for which they were instituted.

At the Kybybolite Experimental Farm on November 10th the Manager (Mr. L. J. Cook) conducted a party of about 400 visitors over the experimental fields. Among the party were Hon. M. McIntosh (Commissioner of Public Works), Messrs. M.

Cameron, M.H.R., V. G. Petherick, R. W. R. Hunt, Ms.P. (members for the district), several members of both State Houses, Prof. Perkins (Director of Agriculture), Dr. A. E. V. Richardson and S. Shepherd (Advisory Board of Agriculture), and many visitors from Victoria.

Throughout the day occasional addresses were given at the respective experimental plots by Messrs. W. J. Spafford (Deputy Director of Agriculture), H. B. Barlow (Chief Dairy Instructor), R. C. Scott (Supervisor Experimental Work), C. F. Anderson (Poultry Expert), and L. J. Cook. Dr. A. E. V. Richardson (Director of the Waite Agricultural Research Institute) explained the experiments with pasture plants which are being conducted at Kybybolite in conjunction with the Waite Institute.

The catering arrangements were in the hands of the Kybybolite Women's Branch of the Bureau and the proceeds of the day's business will be devoted to the building of a hall in the district.

The Visiting Day at the Berri Experimental Orchard was held on December 4th, when Mr. N. S. Fotheringham (Manager) explained to 150 visitors the scope of the work at this institution, and with the aid of printed tables he indicated the results of various classes of experiments over a series of years. Growers along the River Murray are very much impressed with the work of the orchard and very seldom miss an opportunity of viewing for themselves the progress of the various tests with vines and fruit trees.

Mr. W. R. Lewis, on behalf of the Berri Branch, welcomed the visitors, among whom were Messrs. J. B. Murdoch (Advisory Board of Agriculture), Geo. Quinn (Chief Horticultural Instructor), F. R. Arndt (District Horticultural Instructor), and A. V. Lyon, of the Merbein Research Station. In the evening the Chairman of the Berri Branch (Mr. E. R. Moss) presided over a meeting, at which Mr. Geo. Quinn spoke on Frost Prevention as indicated in the recent trials at Light's Pass and Mr. Lyon dealt with the preparation of dried fruits for the London market and the treatment of downy mildew.

UPPER NORTH DISTRICT.

(PETERBOROUGH AND NORTHWARD.)

BLACK ROCK (Average annual rainfall, 12.57in.).

August 17th.—Attendance, 8.

SIDELINES.—Mr. W. Cozens read the following paper:—"The most profitable sidelines for this district are sheep and cows. For the average farm I suggest a flock of about 300 sheep of mixed sexes, about 50 per cent. of each sex. The ewes should be mated to good rams, thus maintaining the strength of the flock. I recommend Merinos for this district; they are better wool producers and do not trouble the fences like the longwool breeds. At the end of the year, if the flock is not too large, the oldest ewes and wethers should be sold. The next best paying proposition is cows. Eight or nine good cows should be kept on the farm, to calve at different periods, thus having fresh cows in all the year round. The Friesian and Jersey are good breeds for milk and cream, but the Shorthorn produces a larger calf, which sells much better than that of the smaller breeds. Always breed from a pure bred bull if possible. Pigs can be raised at a profit if looked after and fed in the proper manner. Each farmer should have two or three good sows, which should have two litters each year. The Large White-Berkshire cross produces a good type of bacon pig, which grows very

quickly. Crushed grain and milk is the most economical feed for pigs. They should also have a small paddock for exercise. Another very satisfactory sideline is poultry; the best breed for the farm is the Black Orpington, the hens being excellent layers and good table birds." (Secretary, R. Kitto.)

WEPOWIE (Average annual rainfall, 12.46in.).

July 3rd.—Attendance, 15.

FARM CROP INSURANCE.—Mr. L. Jasper read a short paper on this subject. He emphasised the advisability of covering the crop against "hail and fire," so that in the event of damage the farmer had something to carry him on instead of a complete loss if destroyed uninsured. Members generally agreed with the principle, but stressed the point that premiums were excessive—in instances almost prohibitive—and for crop insurance a reduction should be made, for no person would knowingly destroy his crop. Different districts should have different scales of charges, for a district without railways and picnickers, &c., risks of fire were not at all great.

July 31st.—Attendance, 12.

CROP ACREAGE REDUCTION IN AUSTRALIA.—Mr. T. Orrock read the following paper:—"Much prominence has been given in the press recently to the proposal that the main wheat-growing countries of the world should consider a compulsory limitation of wheat production. Apparently this has been suggested with the object of reducing the surplus of wheat and thus forcing up prices. Quite a number of prominent men consider that the plan should be adopted in Australia. Some of the reasons advanced are satisfactory from a farmer's standpoint, provided prices rose so that as much revenue would be received from, say, 750 bags as from 1,000 at present prices. If a manufacturer finds he is over-producing, he immediately reduces hands and the taxpayer has in many cases to support more unemployed. If the acreage of wheat were reduced 25 per cent. in Australia, the farmer might receive more value for his produce, but with the extra time at his disposal he would be able to handle the whole process, from planting to delivering the crop, without employing the usual extra labor. Less labor would be needed at the sidings, there would be less railway revenue, and reduced handling and shipping at the ports. Then, if the object of using up the world wheat surplus was achieved, wheat prices would be forced up so that all the extra unemployed that had been forced out of work by reduced production would have a hard time. As a community

ALSO MANUFACTURED—

Blood Manure

Bone Manure

we should protest against such a procedure in this country. Another reason why Australia should continue to grow as much wheat as possible is because of the ever-increasing markets of the East, and the fact, according to statistics, that averages of the United States of America and Canada are already down 10 per cent. According to official reports from Japan, Australia exported 684,309 short tons of wheat to that country in 1932, out of a total import of 829,562 tons, increasing her shipments by 114,023 tons over 1931. Australia's proportion represented 82.49 per cent. for 1932 of Japanese imports, compared with 71.05 per cent. in 1931. Further, China is also increasing imports of our wheat and flour. Shipments of wheat and flour to these markets have doubled during the last 12 months, and are developing at a rate that no one in our country anticipated. Australia has never had a surplus of wheat worth mentioning, and if a portion of our population find it hard to buy bread with a surplus in the world, how would it be if this surplus never existed? Wheatgrowers should resist in every way the suggestion of limiting production. Keep on sowing more and more wheat. The time is not far distant when there will be a shortage of wheat all over the world." (Secretary, E. Roocke.)

MIDDLE-NORTH DISTRICT.

(PETERBOROUGH TO FARRELL'S FLAT.)

BLYTH (Average annual rainfall, 16.77in.).

September 22nd.—Attendance, 12.

"At what stage should wheat and oats be cut for hay, and what are the best methods of stooking and stacking."—Mr. A. Schulze, in the course of a paper on this question, emphasised the need for preparing the binder before entering the crop, and to have everything in perfect working order. Wheaten hay should be cut just when the grain was leaving the milky stage. Oats could be left a little longer, because he desired more grain. The hay should be stooked soon after cutting, and left in the stooks for about 2 weeks before carting, the length of time depending on weather conditions. When stacking, the sheaves should be placed with heads out, the roof with the butts out, and the stack covered with straw as soon as possible. The higher a stack could be built the better, because of greater weight; and mice had greater difficulty in entering a tightly-built stack. (Secretary, R. Eime)

KOOLUNGA (Average annual rainfall, 15.40in.).

August 29th.—Attendance, 15.

Mr R. Bentley read a paper dealing with the care of the brood mare at foaling. He stressed the need for having the mares under observation as foaling time approached, and dealt at length with measures that were necessary in the event of a mal presentation of the foal. (Secretary, I. Jones.)

KOONUNGA.

June.—Attendance, 17.

PESTS AND THEIR EXTERMINATION.—Mr. J. Helbig read the following paper:—"Rabbits were imported into Australia for the purpose of meat production. However, the climatic conditions were so favorable for their multiplication that they very soon got beyond control, and instead of a source of revenue they became a pest. In the early days a rabbit canning factory was established in Eudunda, in those times which did quite a good trade. It was chiefly on account of the rabbits that most of the farmers left the tablelands. Extermination of rabbits was a very serious problem in those days. When I was a lad of 14 my father was share farming on the Balden Estate, and some of the farmers that were there before us told us that the damage done to their crops was so serious at harvest time that every morning they would have to start chains further into their crops because of the ravages done by the rabbits during the night. All the large dams on the run were fenced in with wire-netting, in two corners of which a V-shaped inlet was provided with a round opening in the inward corner into which a 2ft. long funnel-shaped netting spout was inserted to stand about 18in. above the ground at the end; through this little spout the rabbits could get in for a drink, but could not find their way out. They accumulated in such numbers inside the fence that after being killed loads of dead rabbits had to be carted away every morning. Later on again it was discovered that a mixture of bran and phosphorous was a very effective remedy to get rid of rabbits. The mixture was made into little lumps the size of pigeon eggs, and towards evening men on horseback with bags full of baits around their shoulders rode around the run and spread them about the warrens. The method of poisoning was very thorough, and in a very short period the rabbits were cleared out, also opossums. Hunters told me that where they used to get 200 or more opossums in a night they had a job to get a dozen or so after the phosphorous poison. Another introduced pest was the fox. It was calculated that

the fox would keep rabbits in check, but he also soon proved a pest. The eaglehawk was also a serious pest; they played havoc with lambs and poultry. The crow has a particular fancy for fresh eggs on the farm. Yet another pest imported from abroad was the starling—also with a good intention—to destroy the tick on sheep, but like all the other pests it was not satisfied with what was intended for it. Cherries, grapes, and other fruits were more palatable. The destruction of the starling is one of the most serious problems of fruitgrowers, and should receive serious consideration from the Agricultural Bureau. Also the Government should take up this matter seriously. Starlings are very hard to poison, and the only reasonable chance of checking them seems to be to destroy the eggs and young ones at breeding time. It might be possible through the Agricultural Bureau to form bird destruction clubs, raise a levy of so much per acre on all fruit and grape growers, and with the funds available pay a bonus on all eggs and heads collected; the menace is becoming so serious that this matter should not be treated lightly. The same applies to sparrows and also grass parrots with the exception that they can be more easily poisoned. The best time for poisoning is seeding time; after having harrowed the land strew good clean wheat over the top, especially near bushes where birds harbor. Let them eat it all up, and then repeat the procedure with a few packets of poisoned wheat. The minors and silver eyes are also troublesome pest; they are hard to poison, and shooting seems the only remedy. Ticks on horses and cattle are not common pests in this district, and only occur on rare occasions. They are best checked or destroyed by mixing lard or fat with a little kerosene then rubbing the animals with same. Ticks on pigs are of a more serious nature and more common, but are very easily destroyed by brushing the pig with some waste motor oil. It is also a good plan to have a post in the centre of the piggery with old ropes or bags nailed around it and same well saturated with oil. A pool of water with oil poured into it, and where they will wallow, will keep them clean. The sheep tick is another very serious pest. Sheep can be kept entirely free from tick by thoroughly dipping every year with a reliable dipping powder or liquid. Large sums of money are annually expended by householders for the extermination of flies. One of the most common means of destroying the flies is by hanging up glued flypapers to which they will stick. Another common method of destruction is by spraying with prepared fluids. Rats and mice are pests that seem to appear periodically and do an enormous amount of damage. Mice can be easily destroyed with poisoned wheat or other poison, but rats are more difficult to get at because they are particular and cautious. One way to get them is to pour good wine in small cups for several nights, then later dose the wine with strychnine, and the result will be surprising. Rats are exceptionally destructive in sheds without floors; they also do immense damage in haystacks where they are very difficult to destroy, but very often they mysteriously disappear as suddenly as they seem to arrive." (Secretary, G. Cartwright.)

MURRAYTOWN.

August 25th.—Attendance, 12.

A paper was read by Mr. F. Tregenza on "Efficient Farm Working," in the course of which he said that it was better to concentrate on doing a small area properly than to try large areas and slum the working. In the discussion which followed, Mr. Starr said that there was no inducement for a farmer to make an extra clean sample when harvesting, because he only got the same price for clean or dirty wheat when selling. He thought all wheats should be graded. Mr. Bleischke asked what depth the writer fallowed, and Mr. Tregenza replied 3ins. to 3½ins. Mr. Clogg said that if rains held off until late in the seeding period it was practically impossible to kill all weeds if the crop was to be sown in reasonable time. Mr. Joppich spoke of keeping all work done up to time in its season, and also re the cleaning of wheat for seed. The Hon. Secretary said that if it was right to dock wheat under f.a.q., then the merchants should pay extra for any over the f.a.q., because to make a seed wheat sample from the header a quantity of wheat would be blown over the tail of the winnower. Mr. Ryan said that to make a perfectly clean sample all wheat should be put through a winnower before being taken off the farm. (Secretary, E. Pitman.)

LOWER-NORTH DISTRICT.

(ADELAIDE TO FARRELL'S FLAT.)

SUTHERLANDS (Average annual rainfall, 10.82in.).

August 3rd.—Attendance, 85.

The meeting took the form of a debate between a team of three members of the Brownlow Branch and three members of the Sutherlands Branch on the subject "That Sheep are of Advantage on the Average Murray Flats Farm." The Brownlow team debated the affirmative and Sutherlands team the negative, speakers being as follows:—Brownlow—Messrs. G. H. Biar, A. O. Steinborner, H. Semmler; Sutherlands—S. Baehnish, V. Weis, W. Twartz. Mr. Charles Brooks acted as adjudicator, and gave his decision to the Brownlow team by a majority of 15 points. Mr. Biar contended that the average Murray Flats farm would consist of approximately 800 acres, and 100 sheep could be kept as a sideline. The cost of making the farm sheepproof would be covered by the return from the sheep in the first year. The return from 100 sheep in a year with wool at 7d. per pound and an 80 per cent. lambing—lambs valued at 10s. each—would be £35 for the wool and £40 for the lambs. Mr. Steinborner thought sheep were better than any other livestock for short grazing and keeping fallows clean. Mr. H. Semmler said sheep would have feed for six months on stubble which would otherwise have been burnt off. The fact that a majority of farmers kept sheep was ample proof that it was a profitable investment. Mr. Baehnish said prices for lambs and wool were so depressed that farmers were turning to more profitable sidelines such as dairying and poultry keeping. Mr. Weis said farmers could make more profit by keeping dairy cows than by keeping sheep. Oats could be grown and fed to cattle, which would not be possible if sheep were grazing on the land. Farmers were at present living on their weekly return from the sale of butter and cream. Mr. Twartz said the time used in the care of sheep was a great loss to the farmer. Sheep were a false investment because of the expense for beginners due to the erection of sheep-proof fences, woolsheds, dipping arrangements, and erection of yards. (Secretary, E. Schiller.)

STOCKPORT (Average annual rainfall, 16.88in.).

July 27th.—Attendance, 12.

THE FARM GARDEN.—Mr. R. Koch read the following paper:—"The creation of a garden and orchard on farms in this district is made somewhat difficult, because water of a suitable quality is not available during summer, but it is not impossible. For instance, fruit and citrus trees can be grown with a fair degree of success without artificial watering, provided that during the first year or two they are given special attention during summer. The best time of the year for planting any fruit or orange trees is during July and August. Most of the cold of winter is escaped, while in an average year spring rains will give them a fair start. Orange and lemon trees when bought from the nurseries are generally dug up with a little less than a cubic foot of soil left on the roots, about which is tied some thin hessian. Providing this soil is there naturally it should on no account be removed before planting. The best way to plant the tree is to dig a hole about 2ft. square and 2ft. to 2ft. 6in. deep. If the clay is rather shallow it should be removed from the bottom of the hole and substituted with good soil or broken-up bones and crockery. After filling in the hole to within about 1ft. or 9in. of the top the tree should be placed in the hole with the soil and hessian complete and firmly pressed down. During the first summer or two it may be necessary to water the trees at intervals. The best way to do this is to take the surface soil away from around the stem of the tree for a distance of about 2ft. and then fill the miniature dam with water; when it has properly soaked away mulch the soil which has been watered and replace the surface soil. This tends to keep the roots well down and it will be found that a given amount of water will do more good in this way than if it is poured around the tree at random. For citrus trees it is necessary to keep them protected from strong winds. Quite an inexpensive breakwind can be made from titree. If care is taken in selecting straight brushes and the same are woven tightly together between several wires and then neatly trimmed at the top, it will not be unsightly. One of the most important items in the growing of fruit trees is the cultivation of the soil. During the latter part of winter the soil in between the trees should be ploughed to a depth of about 5in. or 6in. It should be harrowed, and after every rain in summer worked over with a cultivator-harrow or garden cultivator. Vegetables can be grown with a fair degree of success in the district during the winter, and cucumbers, beans, and tomatoes can be grown during summer providing suitable water is available. The best time for planting potatoes is the latter part of July. A patch of good soil should be

selected to which has been applied a liberal dressing of stable manure. The soil should then be ploughed or dug to a depth of about 6in. and the potatoes planted. If the ground is ploughed the potatoes are planted in the furrow, taking every third or fourth furrow, if a single furrow plough is used. The ground should be harrowed two weeks after planting. After the potatoes are up and fairly well established, the soil in between the rows should be cultivated after every rain, taking care not to disturb the roots and young tubers. Cabbages, cauliflowers, swedes, lettuces, beetroot, onions, &c., should be sown in seed-boxes, and when the plants have grown to a suitable size, planted out. The soil must be kept well cultivated and free from weeds. Carrots, radishes, turnips, &c., should be planted in well-worked seedbeds and subsequently thoroughly weeded. Cucumbers and beans should be planted in a prepared trench or plot and seed placed about 6in. apart, sowing seeds which have been sprouted, damp flannel being used for preference. With tomatoes it is necessary to first raise seedlings and then transplant in rows about 1ft. 6in. apart. In order to get the best results with tomatoes they should be trained on a low trellis. This prevents the fruit from rotting and induces better cropping. Melons, trombones, and marrows and similar vegetables can often be grown with reasonable success without watering, providing the soil is suitable and properly cultivated. To properly look after a garden takes no small amount of time, but most people will find their patience well rewarded. A neat and well-kept garden and orchard helps to beautify any farm homestead as well as being a considerable saving in the form of greengrocer and fruiterer's bills." Mr. D. Higgins read a paper, "Calf Rearing." (Secretary, L. Klaffer.)

THE ANIMALS AND BIRDS PROTECTION ACT AND ITS RELATION TO AGRICULTURE.

[Paper read by E. Boehm, Sutherlands, at the September meeting of the
Greenock Branch.]

Most people have a very vague and nebulous idea of the real aim and object of protective legislation, and in this paper it is my intention to justify the existence of the Act, and also to acquaint you with certain facts concerning the economy of South Australian animals and birds—especially referring to their bearing on the man on the land. The object of the South Australian Animals and Birds Protection Act is to prevent the wholesale slaughter or exploitation of unique, rare, and interesting native animals and birds. In the early days hundreds of thousands of interesting native animals were destroyed annually in many districts, and quite often without adequate reason. While some kinds were able to hold their own against the warfare which man waged against them, others were not able to do so, and therefore rapidly disappeared. It was therefore found necessary to place legislative restriction on such wholesale decimation, and the Act under review was passed and became law. As regards birds, trappers formerly captured thousands of some kinds, and they were sent to Europe. If this had been permitted to continue a number of species would have died out altogether before very long. The attractive prices which some kinds realised overseas acted as a stimulant to bird-catchers, and it will be seen that without protective legislation all that would ultimately have been left of some of the most sought after ones would have been a few dried and stuffed skins in our museums.

Wholly protected animals in this State at the present time include the different species of bandicoots, animals ranging in size from a little bigger than an ordinary rat to the size of a rabbit. They are all marsupials, and belong to the pouched group of mammals. Their food consists of vegetable matter and insects. Many years ago bandicoots were numerous in the southern districts of the State, but now they are practically extinct over most of their former habitat. A few still linger in the Mount Lofty Ranges, on Kangaroo Island, and in the Far North. One kind lives on Nuyt's Archipelago in the Great Australian Bight and off the West Coast. None of the bandicoots are of economic importance nowadays because they are far too rare.

The banded anteater is another protected animal. It is about the size of a rat, and is of a rusty color with whitish transverse bars. The tail is bushy. This interesting marsupial became extinct many years ago, and all that is left are a few specimens in our museum.

The duck-billed platypus—a curious animal which lays eggs in a burrow in the banks of the stream which it frequents—is exceedingly rare, if not extinct, in South Australia. There may be a few families living in the extreme South-East, and in any case they do not harm anything man needs, and therefore merit their protection. Dormouse opossums are also protected. They are tiny rusty-brown creatures about

the size of a mouse, and live in hollows in trees. They are of no economic importance. The same remarks apply to the flying squirrel and the native bear. The native porcupine or echidna feeds on ants, and does not interfere with anything produced by the agriculturist. It is oviparous or egg-laying like the duck-billed platypus, and is one of the most interesting and primitive creatures in the world.

WALLABIES AND OPOSSUMS.

Other wholly protected species are rock and toolache wallabies, both of which are almost extinct, and protection came too late to save this exceedingly beautiful wallaby. White kangaroos, which are also protected under the Act, do not represent a separate species.

The only wholly protected animals on which there can be any debate on economic grounds are the opossums. In districts where fruit is grown the bush-tails do a certain amount of damage when they become numerous, but as they only breed once a year and produce only a single offspring at a time there is no fear of these multiplying rapidly and developing into an economic menace within a few years. While I admit that the brush-tailed opossum is one of the best known of Australian marsupials, and the only one that appears to be adapting itself to the advance of human enterprise, one cannot lose sight of the fact that during the open seasons of the past which, it must be borne in mind, coincide with the period when the young are still dependent upon the mothers, they have been ruthlessly slaughtered to supply the demands of the skin trade.

In consequence, their numbers have been very much depleted during recent years, in spite of occasional reports from a few isolated areas to the effect that they are extremely numerous and are proving a great pest. Such reports are nearly always exaggerated, and are only an attempt to have an open season declared so that those people who wish to make a few pounds out of skins may do so at the price of many interesting and distinctively Australian animals.

I shall now deal with the animals which are only partly protected under the Act. Fallow deer are not native to Australia, and are not likely to become a pest in the State. They are protected between July 1st and December 31st. Kangaroo rats are protected for the same period, yet they are extinct in the agricultural areas, and there is no possibility of their establishing themselves again. A limited number of these interesting animals is still to be found in the Far North. Wombats are protected for only six months of the year, yet they are fast disappearing, and may become extinct in the settled districts before very long. They still have a stronghold on a few stations in several districts, but it is a precarious hold, and total protection should be granted to them.

Undoubtedly the presence of numbers of wombats in the more densely settled areas would be undesirable, particularly as they dig holes and heap up a large quantity of soil and stones, but there are vast tracts of country where they could live without doing considerable damage.

KANGAROOS.

Kangaroos are protected from October 1st to March 31st, except on Eyre's Peninsula, where the protection comes in the period between March 1st and July 31st. In some districts kangaroos are still numerous enough to constitute a pest, for they do considerable damage to crops, but where the State as a whole is concerned the protection accorded them is inadequate. And I will say the same of wallabies, of which a number of kinds were found in the State in the early days, but which are now nearly all extinct except on Kangaroo Island. As in the case of the opossum the does of the kangaroo are killed during the open season when the young are still dependent upon them, so that the destruction is doubled. The abundance of kangaroos in a district does not give a true indication of the species over a large area. Favorable conditions in a limited area will cause animals from the less favorably situated districts to migrate to it, and thus the number is increased. Wholesale slaughter in this area where the animals are numerous means a reduction of the number in all the adjoining areas. This is one of the chief reasons for the rapid disappearance of certain kinds of animals. They concentrate in a favorable locality in bad times, and owing to the large number in that locality they are slaughtered.

It seems to me that even kangaroos should be totally protected over the whole State, because they are becoming rarer year by year. There is no reason to justify the open season other than getting skins for sale and indulging in the sport of killing.

The Animals and Birds Protection Act enables the farmer to destroy kangaroos if they are damaging his crops in the closed season, providing that no part of the animal is sold. This protects the landowner, and there is no excuse for an open season other than making money by the sale of skins and having the pleasure of murdering interesting and characteristically Australian native animals.

Species which are unprotected include the fox, rabbits, hares, wild dogs, rats and mice, and domestic cats run wild. Seals are not protected except within Spencer's and St. Vincent's Gulfs, Pearson Island, and north of a line from Cape Catastrophe to Cape Borda; thence to Cape Hart and the Murray Mouth. Rats and mice have little in their favor, but it is regretted that several interesting and rare native kinds do not enjoy Legislative protection. They live outside the settled districts, and do not harm anything we need. Domestic cats run wild perform a signal service where rabbits are numerous, but they are doing a tremendous amount of harm by slowly but surely exterminating some of the rare small native animals and birds. The domestic cat run wild vies with the fox in being one of the most baneful disturbing influences now at work among our small native fauna. It behoves every landowner to discourage the cat and the fox for these reasons alone. Seals are unprotected because fishermen claim that they prey too extensively on useful fishes, but naturalists generally feel that our seals should be totally protected.

BIRDS.

The great majority of the 374 kinds of birds recorded for South Australia are wholly protected under the Act. They are either insectivorous, carnivorous, granivorous, fructivorous, or honey-eaters. Those which are insectivorous deserve every bit of protection they can possibly get. We have not the severe winters of Canada and Europe, and therefore we need the insect-eating birds to keep the different kinds of insects in check, otherwise they would increase phenomenally, and disaster would overtake agriculturists. The quantity of insects which some birds eat is remarkable, and one needs to know the full facts before their real value can be appreciated. Most of the protected species are insectivorous. The carnivorous birds include hawks, owls, and butcher birds. They do a valuable service to the maintenance of Nature's balance by preying on sick birds, thus preventing the spread of disease, and by controlling mice, rats, and rabbits. It is a grave mistake to regard all hawks and owls as pests, and to condemn all kinds for the misdeeds of a few.

The granivorous birds include finches. None of the native finches are harmful, and they therefore deserve protection. The fructivorous species do not find favor with orchardists and gardeners, but fortunately none of them do any considerable damage. Honey-eaters—which include several parrots—destroy honey-dew, the exudation of scale insects. The sooty mould of citrus trees breeds in this honey-dew, and by feeding on it the birds assist the gardener to combat sooty mould fungus.

THE MOST CERTAIN CHEAPEST. AND EASIEST

Method to Destroy

RABBITS

is with the

POISON CART

provided you use

RABBIT POISON

If you mix it double strength you will get the skins alongside the trail.

It can also be spread by hand.

S.A.P. has, for 35 years, been the most successful Rabbit Poison. This is due largely to the fact that, in this well-known poison, the phosphorus is so finely and evenly divided that every bait, and every part of the bait, is equal in strength.

A. W. SANDFORD & Co., Ltd.

75, Grenfell Street, Adelaide.

Partially protected birds are the maned goose and ducks of different species. They are protected between August 1st and February 14th. Some of the ducks are very rare, and should be on the totally protected list.

Quail of all species are protected from August 1st to February 18th. While the stubble, button, and painted quail are common, other kinds are very rare, and should not be permitted to be shot. Snipe are protected between March 1st and September 30th.

Totally unprotected species are the blackbird, crow, corella, galah, sulphur-crested cockatoo, cormorant, starling, sparrow, greenfinch, goldfinch, musk lorikeet, Adelaide roseella, silvereye, goshawk, eagle, blue mountain parrot, and native hen.

Mr. W. D. Bruce (Chief Inspector of Fisheries and Game), who was asked to comment on the above paper, said the fox was largely responsible for the destruction of many of our small animals and ground birds. Our few remaining specimens of the khola or native bear had also been taken by foxes, and this pest had very considerably reduced the numbers of scrub and rock wallabies. The only place in the State where these animals were in any great numbers, and where they had increased to such an extent as to become a nuisance to farmers, was on Kangaroo Island. There was no reason why wallaby skins should be taken for gain, because the skins were practically worthless, and it did not pay to market them.

The provisions of the Animals and Birds Protection Act empowered every land-owner or occupier of land to be a protector of our native fauna, and the Act made it an offence for any person to enter or be upon any land—other than Crown Lands—for the purpose of taking any animal or bird without permission of the owner or occupier of the land, so that any person who was desirous of making his holding a sanctuary could do so under this provision.—[Ed. Journal.]

INSURANCE.

[Paper read by Mr. L. Burton at the October meeting of the Saddleworth Branch.]

This is a common subject of discussion, and affects all producers, whether it be life, fire, burglary, accident, employer's liability, or some special risk. The most common is fire insurance and most people with any property at all have fire cover. It is very cheap and well worth the few shillings a year involved. Fire insurance costs from 4s. less 10 per cent. discount per £100 upwards, the rate increasing for more inflammable classes of property and their contents. Also factories or stores in the vicinity of one's property which may contain the means of starting a fire.

No fire insurance risk is given unconditionally, and policy holders should read through the conditions set out therein. This is particularly necessary with new companies who offer enticing cover to get business. The older firms have a set policy and do not deviate from it. The first thing in taking out a fire policy is to give a true description of the property to be covered; any misrepresentation in the case of fire will cause the claim to be disputed. For instance, do not say the division walls of the house are brick and stone, when perhaps one is matchboard. Do not over-insure. The fire insurance companies, as an association, employ highly paid officials (fire assessors) and in the event of the destruction of a building, &c., by fire an assessor makes a valuation of the damage. If the house is covered for £1,000 damages by fire, and the property is only valued at £500, then in the case of fire and complete destruction the assessor's valuation of £500 will be paid, and the extra premiums that have been paid for a £1,000 cover will be a waste of money. It is better, when taking out a policy, to make a conservative valuation of the property to be insured and not insure for more than that.

EXTRA RISKS AFTER POLICY HAS BEEN TAKEN OUT.

This is a point often overlooked by policy holders and it should be attended to at once. By not advising the company the policy holder leaves himself open to having the policy declared void in the case of fire. These extra risks involve additions or partitions to the house or property of inflammable material, such as wood. If, for example, the back verandah is enclosed with iron lined with wood or with weather-board, and a bathroom and heater is installed at one end, this is an additional risk and the company should be advised so that the description of the property is true and up to date. If electric light and power points are put in the home, advise the company immediately; this is an additional risk. The company will stamp the policy "Electric light and power instalment allowed and fire from this source covered by policy." The same applies to the use of and installation of petrol air plants. In the case of lighting the home with petrol air gas, the companies require that the gas producing plant must be installed away from the house and protection provided between the plant and the house. If the house is covered with one company and the contents

insured with another, advise the companies concerned immediately. Electric light companies and the Postmaster-General's Department always instal current or telephones in accordance with the Underwriters' Association conditions and proper earth wires and lightning arrestors are provided. If the wiring is not in accordance with the regulations it must be rectified. The electric light companies will pass the wiring of any electrician if requested to do so; if it fails to come up to regulations, then they will not instal their meters. Even if a wireless plant is installed make adequate protection by providing the lead in from the aerial with lightning arrestor and an outside earth. These arrestors are cheap and can be installed in a few minutes. Such property as money in notes and coin, deeds, and company scrip for shares, and Commonwealth bonds are not covered by an ordinary policy, therefore do not leave such valuables in a house unless kept in a fireproof safe. Any bank or safe deposit will accept these for safe custody. Loss or damage by explosion is not covered by ordinary risk, so that all ammunition and explosives must be kept in a very safe place. All implements and haystacks should be insured to their market value.

EMPLOYER'S LIABILITY INSURANCE.

This insurance is compulsory and it behoves everyone to see that all their employees are covered. An open policy at a very cheap rate can be obtained from any company and this will cover permanent and casual employees. If any casual labor is employed, even a man weeding the garden or chopping wood for a day a week, or a day a month, see that he is covered with an employer's liability. Many claims have been upheld by the court. A man calls at your farm or house and wants work, and if you employ him for only half a day or an hour or two still makes you liable to pay damages for any accident incurred.

LIFE ENDOWMENT INSURANCE.

The most important feature is to give a correct description when applying for cover. Proof of age is most important, supply concrete evidence such as the production of birth certificate. All questions asked in the proposal form must be true; many a life policy claim has been upset because the original proposal form was incorrect as to answers of vital questions. The payment of all claims is subject to the personal statements made in the original proposal.

ACCIDENT AND SICKNESS POLICIES.

These require special care in complying with the conditions. Most people pay their premiums and believe that they have full protection. It is only when they come to make a claim that they realise that certain printed conditions on the policy negatives the company's liability in a great many circumstances. Many policies contain a clause reading:—"This policy does not cover injuries sustained while the insured is performing any unlawful act . . . or acting in violation of the rules, regulations, or by-laws of any person, corporation, company, or public authority having power to make same, or otherwise exposing himself to any unnecessary danger or risk." A case under a policy such as this comes to my mind. John Brown took out a policy for £500 containing the above clause. He was fatally injured in a collision between a motor car and a buggy which he was driving. His executors lodged proof of death with the company and a claim for £500—the amount of the policy. The company made inquiries into the cause of death and then denied liability. Their letter of advice to the executors stated that Brown sustained injuries whilst performing an unlawful act, namely, driving a buggy at night without a light and consequently the claim was null and void. The matter went to the Supreme Court in Victoria and the

presiding Judge was asked to give his decision whether the driving of a buggy at night without lights represented an unlawful act within the meaning of the policy. The Judge upheld the insurance company, and in conclusion stated "I regret that it is not obligatory on the company to bring under the notice of the proponent at the time the policy was taken out and to inform him of the actual protection afforded. The clause exempts the company from liability if injury occurs while any breach of the traffic regulations, however trivial, is being committed, whether the breach be the cause of the injury or not. When I reflect that we are so hedged in with regulations to-day as to make it scarcely possible for any of us to avoid committing a breach of some regulation with the possibility of injury while doing so, it seems to me that an accident policy in the terms of this one affords no protection in many cases." Policy holders must make a point of reading their insurance policies, and have any part that is not clear to them explained by some experienced person. This is absolutely necessary when the insurance is taken out with some company that is not one of the old established institutions. Many of the new insurance companies have so worded their policies that they do not give the degree of protection that the assured believes he is receiving. What appears to be a very complete policy is very often whittled down by printed conditions in the policy. So read through all your policies and understand the conditions and you will have a good idea of the actual protection the policy gives you. Sickness policies contain dozens of complaints which exempt the companies and this branch of insurance should be left to lodges.

COST OF INSURANCE.

I am a firm believer in life assurance to provide for old age or the family, fire insurance, employer's liability, and motor car comprehensive policies. The cost is small. Every farmer should insure his improvements to at least half their market value. Crops and haystacks are essential items for insurance. Besides the peace of mind that the cover affords, the cost is trifling. In crop insurance it would take over 100 years of premiums to make up the loss of one fire. A house property would take at least 200 years of annual premiums to pay the loss of one burn out, &c. When farm incomes are small, there are not many farmers who could withstand the disaster of being burned out. Cover the crops for a reasonable amount, also improvements, &c. Do not over-insure; it is an unnecessary waste of money. Careful valuations on the conservative side is what the companies will pay in the event of a claim.

LAMBS FOR THE FREEZERS.—Paper read by Mr. G. Young:—"The Merino ewe if used for the mother should be large-framed and plain-bodied. Merino lambs, if they mature early, sometimes develop into quite attractive export carcasses, but the majority of them, by the time they reach maturity, become leggy and long in the neck and cannot compare with the short, thick carcass produced by the Down cross. Last year endeavors were made to popularise the pure Merino on the English market, but this will be a difficult job. The South Down crossbred lamb, or other Down cross, is firmly established in England, and the only hope of successfully marketing the pure Merino is to ship separately under a special Merino brand and push the sales by the use of a special propaganda. Even then it is doubtful whether the prices realised would compare with those obtained from the attractive Down cross. As regards the sire for the export trade, the South Down stands alone. The experience at Port Lincoln Freezing Works proves that when the Merino dam is crossed with a Down sire, such as the South Down, Shropshire, or Suffolk, a very good export lamb is obtained. The South Down especially has been outstanding, and this is the sire on which New Zealand and Victoria have built up their export trade. The average age

of maturity is 3½ to 4 months old; when a lamb is over 5 months old it is generally considered that it is not then a spring lamb for export. It then has a tendency to lose its bloom and become "hoggetty." The dressed weight required is 28lbs. to 32lbs. During the past two years the demand has become stronger than ever for light weight lambs. People generally are not rearing big families and their spending power is very limited. The result is that not only with lambs, but with all classes of meat, the demand is universally for small joints. During the last few months in London third grade light weight lambs have been quoted above first grade heavy weights. The difference between live and dressed weight varies according to breeding, condition, and travelling. Various tests have shown that, generally speaking, a dressed lamb loses 50 per cent. plus 2lbs. of its live weight; a lamb weighing 60lbs. live weight should dress approximately 28lbs. This does not always follow. If lambs are two or three days away from their mothers before killing, they may lose 50 per cent. and 4lbs. or 5lbs. The killing season on Eyre's Peninsula is much later than the other side of the gulf. At Port Adelaide killing is commenced about the end of June, and sometimes in September at Port Lincoln. The killing season lasts about three months. It should be possible to have spring lambs ready in August, but if the season is extended beyond November grass seeds become troublesome. Lambs are preferred in wool, as an assurance is then given that they have not been taken off their mothers. If lambs are shorn they must not be separated from their mothers any longer than is absolutely necessary. Two or three weeks should then elapse before they are killed to allow any surface bruising or shearing cuts to disappear. There is always a danger of the lambs receiving a setback through being shorn. Cartage by rail has been proved by experience to be preferable to cartage by motor lorry; the percentage of bruising on the railway has been very small compared with the lorry. This is sometimes due to carelessness on the owner's part. The cost by rail is approximately 1s. per head per 100 miles, which compares favorably with motor transport. The advantage of the lorry is that the lambs can be picked up at the yard and there is no further handling. Handling is very important; the lambs should not be grabbed on the back to be caught. This leaves bruises; they should be caught by the leg and with two men to load and clasping their hands under the brisket the lamb is lifted gently into the lorry. This applies where there is no ramp or race. The blowfly pest should be treated with something that will not cause hard lumps to remain on the carcass; kerosene and oil is very effective and soothing. The London market at present is much more favorable than at this time last year, but it is impossible to forecast the future. Skins are selling better. The indications are that returns will be better than last year." (Secretary, P. Lange.)

DRAINING SWAMP LANDS.—The following paper was contributed by Mr. G. Gardner:—"In times of low prices for all products off the land it is necessary to make every acre as productive as possible, and to carry the maximum number of livestock. There are many acres in this and surrounding districts that are of very little value in their present condition, growing nothing but rushes, cutting grass, and native couch grass. There are hundreds of acres of this class of country in patches of from two to 20 acres. These flats and gullies are waterlogged, and in many cases fairly heavily charged with salts, but if some economic system of drainage could be adopted this almost useless land might be made the most fertile part of our holdings. There could be no general scheme because the land to be treated is in separate, disconnected plots, and each plot would have to be treated according to conditions. That would mean a lot of extra fencing and labor, but the small paddocks would be very useful, and if the drainage was successful would soon compensate for the extra work and would enhance the value of the farm. Some years ago I put a small drain through the centre of one of those waterlogged flats and as there was a fair fall it soon washed out and became about 2ft. deep, with the result that the land on either side of the drain for about 3 chains is now well drained and produces a good stand of grass and herbage, whilst the remainder of the flat is still boggy and waterlogged. In the early days of settlement of this district when farm work was done with two horses, or more often four bullocks and a single plough, it was customary to work these wet flats in lands about ½ a chain wide, throwing up the crown and leaving small drains about 11 yards apart. The land so treated grew heavy crops of oats, etc., and gave big returns off small areas. I also advocate more top dressing and the conservation of fodder in the form of ensilage or hay so that stock will be hand fed when rains are late, and not have to put them on the market when there is not much demand for them." Mr. Schultze instanced how a swampy flat was drained and fodders were greater, producing good crops and many kinds of vegetables. Mr. Smart had a good black

flat which a few years ago had been very productive, but of later years had been spoiled by magnesia or salt. He thought it would be impossible to get rid of the magnesia off some patches. Mr. Low cited a case in the South-East where very wet land had been drained by ploughing in very narrow lands and planting clover. Mr. Brennand thought it was a mistake to plough where the salt patches existed, because ploughing increased the salt area. (Secretary, T. Gardner.)

ECONOMICAL FARMING.—Mr. E. Shearer read the following paper:—"Every farmer should take advantage of the benefits to be obtained from such Government institutions as Roseworthy College and the Agricultural Bureau. The rotation of crops for this district should be fallow, wheat, oats. It is impossible to keep fallow clean without the assistance of sheep. A flock of 200 sheep is sufficient for the average farm. Sheep not only lessen the cost of production of wheat on fallowing, but also reduce the butcher's bill to a minimum. The wool cheque (200 x 7lbs. at 6d.=£35) has an attractive value, in that it usually comes along at a particularly depressed period. For economy in the household it is essential that the farmer has a few cows—enough to supply household needs. Three pure-bred cows and a bull eat far less than the usually 10 or so mongrels one too often notices. Compare the herd-testing results in the *Journal* with the housewives' returns and see why pure-bred stock should be kept. To improve the present stock, buy a subsidised bull of good milking strain rather than good cows. One good bull is worth three scrub bulls, which should be sold to the butcher before they are old enough to do any damage. Friesian cows are best for this district. Do not overstock with cattle; sheep have first claim on the feed in the scarce season. It is far easier to feed half a dozen cattle on oat-chaff than it is to handfeed 200 sheep. Pigs are a paying proposition if not kept too long. For the first five months a pig eats about 3lbs. corn per day; this given twice a day with milk and as much clean water as the pig can drink is all that is required. With the exception of the horse, no animal responds to care and surroundings better than a pig. The pigsty should be clean, dry, and protected from heat and cold. One hundred laying Leghorns will give 20doz. eggs for sale, in addition to those used in the home. This is equivalent to 10s. per week. Barnyards lay when the price is low, and are either setting or 'doing nothing' when prices are high. The cockerels should be separated as soon as possible, fattened and used for the table. Infertile eggs are the best for the export market. Hens begin to go back after the third year, so why keep them? If possible a few hens should be penned for breeding purposes and the roosters constantly exchanged for better ones. The fowl shed should be high enough to walk around in; the perches need only be 18in. high and about 2ft. apart. Fowls are early risers, therefore the door should be opened early. Do not forget to shut the door at night to guard against foxes. For economy's sake co-operate with your fellow-farmers. Farmers would be the strongest body in the land if they pulled together for the good of the industry instead of from a selfish individualistic point of view. In two years, if individualism is carried on, the farmer will still be in the same old position of opposing his neighbor instead of uniting and forcing other people to see that the farmer and other primary producers must be prosperous for the world to progress." (Secretary, W. Eason.)

MALTEE.

August 3rd.—Present: 10 members.

PRUNING THE VINE.—Address delivered by Mr. O Chant:—"The Parts of the Vine.—The trunk or main stem arising from the soil supports the framework, lifting it to the desired height above the ground. From this arises the main arm or arms (usually two in the trellised vine) which support the secondary arms and the annual fruiting shoots arising from the secondary arms. These annual shoots or canes bear buds which produce the crop in the following summer, and are called the fruiting wood. At times—when the pruning has been too severe for definite reasons or on account of incorrect judgment on the part of the pruner—shoots develop from the main stem or main arm called 'water shoots.' These indicate that the vigor of the vine has been under-estimated in the number of buds left upon it at the winter pruning. But these water shoots may be utilised to fill a space in the framework of the tree if such is the case, or a properly placed water shoot will afford the opportunity of renewing a secondary arm. Another type of annual shoot grows from a bud on the buried portion of the vine, and is known as a sucker. This has no value except that perhaps the parent vine be damaged very badly, when the case would necessitate the removal of the parent to train the sucker in the former position of the parent vine. This is only adopted when the parent vine was originally grown from a cutting.

Structure of the Shoot or Cane—The annual shoots of the vine particularly, are clearly divided into distinct portions—nodes and internodes. The internode consists of a large central pith enclosed in woody tissue which is in turn contained in a thin closely adhering covering of bark, composed of continuous and closely packed parallel fibres. The node, or thickened portion, holds no central pith, its space being occupied by a wedge-shaped septum which is more compact in character than the fibres which surround it. The bud is joined to the upper end of this wedge-shaped septum at the node, and is protected by the bark being wrapped around it at this point. This non-pithy septum has a distinct value, especially in wet countries where pruners often cut through these woody divisions when severing the canes as a step towards avoiding decay. Physiologists claim that the bud is—for nutritive purposes—primarily connected with the internode above it, in that the bud draws nutriment from this part when it starts to grow in the spring, but whether the vine will be benefited sufficiently to compensate the extra labor involved in severing these dead terminals at the next winter's pruning, is open to question. But the possibility of injuring the grape vine during tillage operations is certainly increased by the long projecting internodes. On the other hand, these terminal internodes are a definite advantage when left at the end of a cane for tying the cane on the wire, for this part soon dies, and growth is not restricted through tying on the wire.

The objects of pruning may be briefly summed up:—(a) To increase the size, appearance, and quality of the fruit. (b) To secure regular crops over a long period. (c) To accomplish both these aims on the most economic lines.

In the application of the art we strive:—(a) To modify the form of a tree to meet the requirements and to counteract unfavorable climatic conditions. (b) To reduce or stimulate the production of wood growth or fruit bearing as the case demands. (c) To remove injured or worn-out parts. It is well to take into consideration the following rules or laws which seem to invariably operate in the growth of plants:—(1) The vigor of a plant or a shoot is dependent upon the leaf surface, i.e., the tree with most leaves is usually the strongest grower. (2) The nearer a shoot approaches the vertical position the stronger will be its growth. The sap in plants flows most freely to the highest point of each shoot. (3) The nearer a shoot approaches the horizontal position so its vigor diminishes. Vertical shoots usually run to wood alone, while those tending towards the horizontal usually produce fruit. This goes to show that fruit bearing is an attribute of moderate weakness rather than of great vigor. (4) The lesser the number of buds upon a branch the stronger will be the growth made by each individual shoot which arises from these buds. Therefore, heavy pruning of the top tends to increase the production of strong wood growth. This is because there is a balance between root and top so that when the top is reduced the roots send up still the same amount of food for the reduced number of buds. Prune the top of newly-set trees. (5) If the root

GRUBBING

IS A ONE MAN JOB

FOR STUMPS LARGE OR SMALL, GREEN OR DRY,
SHORT OR HEAD-HIGH. THE ENORMOUS-POWER OF A
MONKEY GRUBBER

EASILY ACCOMPLISHES THE TASK

Removing the most stubborn obstacles cleanly, with most roots intact.
Easy to handle, simple to operate, expeditious—its only need, regular oiling.
The Standard equipment will clean up everything over 1½ acres from one anchorage.

Each part designed for simplicity, easy handling and long trouble-free service.

system be reduced the vigor of the top growth will be correspondingly diminished. Therefore prune the roots of rank-growing unfruitful trees. When roots are damaged and removed in shifting a tree from the nursery the top should be reduced also to maintain the balance or otherwise stunted growth or decay will result. (6) When a number of shoots are growing at different levels upon the same plant, generally the topmost shoot absorbs most sap and outgrows those below. This gives rise to the practice of pinching out the growing points of the highest shoots on young trees. This lessens this natural advantage. (7) Deformations of any kind diminish the activity of plants or of those plants situated directly above them. (8) Within certain limits the fruit production of any plant or shoot diminishes with increased activity of its vegetation. When a mature tree is forced into making vigorous growth its production of fruit is lessened. (9) The smaller the number of fruits the better their quality and size. This fact is taken into account when pruning the tree. Some fruitgrowers thin their crops while still in a very early stage of development. In this way each fruit receives a larger share of the plant food elaborated.

Season for Pruning.—Winter pruning is usually looked upon as the most important, and is done when the wood has ripened and the leaves have fallen from deciduous trees. The general effect of pruning in this period is to stimulate increased growth when the season of vegetative activity returns. It is of great value in shaping young trees or renovating older trees which lack vigor. Also by reducing growth to get a better shape, &c., the buds are also reduced, and thus the fruit production is also taken into account. Summer pruning is carried out when the tree is in a state of vegetative activity. A reduction of the green parts of a tree tends to administer a check, because it suddenly removes some of the absorbing surface—the leaves. The admission of strong sunlight has a stunting influence because it retards the flow of sap to the extremities of the branches. Fruit bearing seems to go hand in hand with decreased vegetative activity so that summer pruning has been utilised to induce the fruiting habit in trees of strong growth. This early application of summer pruning is useful in giving a temporary check to a vigorous shoot which threatens to outgrow its fellows and thus upset the balance of the young tree.

Pruning Tools.—(a) Pruning Knife: Thin blade which is concave with the handle on the same side convex. Useful for smoothing the edges of rough saw cuts, finishing off the rough ends made by the secateur in forks and sharp angles, and in pruning roots of young trees. Makes a very clean cut. (b) Pruning Shears or Secateurs: The best makes have a strong framework which refuses to bend under very great pressure. In all good types the blade is removable, and can be replaced by a new one costing about 1s. This blade should have no shoulder so that very little lateral pressure will be exerted upon the shoots, thus bruising them for some distance. In cutting a shoot the blade should always be held next to the plant.

Treatment of the Fruiting Wood.—The spur may be defined as a portion of the last season's wood carrying from one to three buds. A rod is a portion of the previous summer's cane possessing from 10 to 16 buds. It must be remembered that rods on strong vines often do not have 10 buds. If it were practicable, it would be simpler to prune all vines into spurs, but the habit of bearing peculiar to each variety must be taken into account. Observations show that on some vines the buds upon the lower ends of the annual canes are the ones which produce flowers, while in others it is the buds situated well out along the cane—these are usually the vines displaying great vigor. Others again produce bunches more or less all over the ripened canes. These observations have led vinegrowers to classify varieties into spur-pruned or rod-pruned types. In practice a vigorous vine of the spur-pruned section can retain a greater number of spurs, and may also carry the full number of buds. But a weak vine of the same variety should have its spurs reduced in numbers, and also each spur may be reduced to one or two buds. If a greater number of spurs are retained than should have been left, a crop of numerous but inferior fruit will be obtained. If the pruning is too severe, dormant buds grow into water shoots or suckers. Generally speaking, for table grapes or raisins, it is desirable to prune hard in order to keep up the quality of the fruit, although water shoots occur with moderate frequency. In the case of grapes for wine making leading authorities affirm that in good strong soils where the vines are vigorous rod pruning is applicable to most of the varieties usually classed among those spur pruned.

Systems of Training.—Grape vines are naturally climbing plants, but under cultivation for economic reasons they are trained either as low bushes or as climbers on trellises. Spalier is the term applied to a trellised vine on which a permanent arm is trained out from the stem at the same height on each side and in the same plane. If more than one pair is retained each are on the same level. Some forms of Spaliers have several pairs of such arms, but such a form is not to be recommended for use excepting to such persons who may desire to follow the work of trellising purely as a hobby. The best and most simple type is to permit one vertical stem only and one pair

of horizontal arms to each vine. The newly planted vine is pruned back to a single spur of one or two buds with a view to inducing at least one strong shoot to arise during the ensuing summer. This shoot should be secured to a stake or upright support as it ascends. The Bordelais Spalier type has been recommended by Professor A. J. Perkins as suitable for the wine grape (certain varieties) when grown in comparatively poor soils. This form is suited to a cheap trellis of two wires with the lower one about 12in. to 15in. above the soil. The upper wire is placed about 20in. above the lower one. The type consists of a stem about 10in. high, and on each side of the stem is a short main branch bearing either one rod and a spur or two rods and a spur according to the strength of the vine. The vine is trained by pruning to one spur at the second winter season, at the same time seeing that the two topmost buds are on opposite sides of the spur and face the wires. The following summer these two buds are encouraged to make good shoots. Next winter both of these are pruned as spurs with from three to six buds each, thus forming the main arms; the resulting growth should give at least two good canes from each arm. In the following winter one of these is pruned to a spur for wood production purposes, and the remaining two are made into canes for fruit bearing during the coming summer. The vine is now formed, and the annual pruning consists of suppressing the previous year's rods, removing all water shoots and suckers, and converting two shoots of the previous summer's growth to a spur and rod respectively on each arm. Strong vines may carry two rods and two spurs. The spur, being reserved for wood production, naturally regulates the framework of the tree, and is in part comparatively permanent in character. The rod is more temporary—fruit bearing. To prevent undue extension the spur should be taken from the cane situated lowest upon the main arm in the direction of the main arm. In the course of time the main arms become impoverished with old scars or become too long, and should be replaced by means of suitably placed watershoots as described previously. (Secretary, V. Schwarz.)

MOUNT HOPE.

August 8th.—Attendance, 8.
